

A SYSTEMATIC APPROACH TO ANALYZING PRE-CLOSURE OPERATIONAL  
PERFORMANCE OF THE PROPOSED REPOSITORY FOR HIGH-LEVEL  
NUCLEAR WASTE AT YUCCA MOUNTAIN, NV

By

Leah Spradley

Dissertation

Submitted to the Faculty of the  
Graduate School of Vanderbilt University  
in partial fulfillment of the requirements

for the degree of

DOCTOR OF PHILOSOPHY

In

Interdisciplinary Studies: Environmental Management

May, 2008

Nashville, Tennessee

Approved:

Professor Mark Abkowitz

Professor James H. Clarke

Professor Frank L. Parker

Professor Michael G. Stabin

Dr. B. John Garrick

Dr. Michael T. Ryan

This work is dedicated to my loving mother,  
who has given me the strength and courage to pursue my dreams,  
and in memory of my father,  
who encouraged me to lived life to its fullest.

## ACKNOWLEDGEMENT

The information presented in this report is based in part on work supported by the U.S. Department of Energy, under Cooperative Agreement Number DE-FC01-06EW07053, entitled ‘The Consortium for Risk Evaluation with Stakeholder Participation III’, awarded to Vanderbilt University. The opinions, findings, conclusions, or recommendations expressed herein are those of the author(s) and do not necessarily represent the views of the Department of Energy or Vanderbilt University.

I acknowledge the support of the National Science Foundation, through an Integrated Graduate Education Research and Training (IGERT) grant, and of Bridgestone Firestone of Americas, through the Bridgestone of Americas Fellowship. I thank my Dissertation Advisers, Dr. Mark Abkowitz and Dr. James H. Clarke, and the remainder of my Committee, including Dr. B. John Garrick, Dr. David S. Kosson, Dr. Frank L. Parker, Dr. Michael T. Ryan, and Dr. Michael G. Stabin, for their advice and guidance. I also acknowledge the assistance offered by members and staff of the Nuclear Waste Technical Review Board, including Gene Rowe, Dr. Bruce Kirstein, and Dr. John Pye. In addition, data support provided by John Thorpe, a DOE contractor, as well as Dr. Tina Gosh, Albert Wong, and John Buckley from the Nuclear Regulatory Commission, is much appreciated.

This report was prepared as an account of work sponsored by an Agency of the United States Government. Neither the United States Government nor any agency thereof, nor any of their employees, makes any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness, or usefulness of any

information apparatus, product, or process disclosed, or represents that its use would not infringe privately owned rights. Reference herein to any specific commercial product, process, or service by trade name, trademark, manufacturer, or otherwise does not necessarily constitute or imply its endorsement, recommendation, or favoring by the United States Government or any agency thereof.

# CHAPTER I

## INTRODUCTION

### **Current State of Commercial Spent Nuclear Fuel in the United States**

#### *Description of Commercial Spent Nuclear Fuel*

Radioactive waste has accumulated due to government operations, including nuclear weapons production, the commercial generation of nuclear power, as well as the medical and industrial application of radioisotopes. The Nuclear Waste Policy Act (NWPA) of 1982 § 2(12) defines high-level waste as the byproducts of irradiated spent nuclear fuel (42 USC § 10101 (2008)). Commercial spent nuclear fuel (CSNF), representing the vast quantity of spent fuel, is fuel that has been irradiated in a commercial nuclear power reactor to the point that it is no longer economically efficient for use. When fuel assemblies reach this point, they are discharged from the reactor core and stored under water at the reactor site in spent fuel pools.

It is important to isolate CSNF from humans and the environment because it is highly radioactive and potentially harmful. When first discharged, an assembly typically generates tens of kilowatts of heat from decaying radionuclides. As the shorter-lived radionuclides decay, the heat produced drops by a factor of 100 for the first year, and by another factor of 5 by the end of the 5<sup>th</sup> year (NAS 2006b). Ten years after it has been removed, the radiation dose rate from standing one meter away from a typical spent fuel assembly exceeds 200 Sv (20,000 rem) per hour (NRC 2002). While radioactivity

diminishes rapidly in the first few years as the shorter-lived radionuclides decay, many of the radioactive elements in spent fuel have long half-lives and remain potentially harmful for long periods of time (e.g., plutonium-239 has a half-life of 24,000 years). Therefore, it must be safely isolated for thousands of years. However, the spent nuclear fuel pools, where the majority of the waste is housed, are only considered temporary storage solutions.

The pool at each commercial reactor was not designed to hold all the spent fuel generated by the reactor over its lifetime. The original intention was to temporarily store the CSNF until it could be sent for reprocessing. However, due to proliferation concern and the inexpensive cost of uranium, the nation's waste management strategy moved away from reprocessing. Only one commercial reprocessing facility had been built in West Valley, NY and this facility ceased operations in 1972 (Salvatori 1996). The suspension of reprocessing was lifted under the Reagan Administration, but no new commercial reprocessing facilities have been built, mostly for economic reasons. To alleviate the load on spent fuel pools, some utilities have implemented on-site and off-site dry cask storage. Although removal of assemblies after only one year is legally permitted, standard industry practice is to leave the assemblies in the pool for at least 5 years before moving them to dry storage (NAS 2006b).

As of 2007, the United States had generated approximately 56,000 MTHM (metric tons of heavy metal) of CSNF from its 100 plus currently operating reactors. Reactors are licensed to operate for 40 years, with an option to apply for a 20-year license extension. Assumptions regarding projected energy trends and the number of license renewals must be made in order to estimate future inventories of commercial spent

nuclear fuel. One projection for total discharges that assumes all of the currently operating reactors are granted the 20-year extensions and run for 60 years, estimates there will be approximately 129,400 MTHM of spent nuclear fuel (BSAIC 2003). The United States (U.S.) inventory of spent fuel may increase beyond this estimate, depending on construction of new reactors. Although there has not been an order for a new plant in 30 years, the nuclear industry is currently preparing to build new reactors. Four applications for combined construction and operating licenses were submitted in 2007, and more are expected in coming years (NEI 2008).

Currently, approximately 15% of the nation's CSNF is in dry storage. The remaining 85% is in spent fuel pools. Storage in spent fuel pools is implemented at the 65 operating reactor sites as well as 8 sites where reactors are no longer operating. While dry storage currently exists at only 22 operating reactor sites and 6 non-operating reactor sites, it is estimated that over the next 17 years, approximately 3 to 4 pools will reach full capacity each year (NAS 2006b).

### ***Dry Cask Storage of Commercial Spent Nuclear Fuel***

When fuel is taken out of the pool, it can be placed in a variety of dry storage containers, referred to as casks. Dry casks are made of steel or concrete and can be categorized as bare-fuel or canistered-fuel systems. The difference in these terms has to do with how fuel assemblies are loaded into the casks. In a bare-fuel system, the basket in which the spent fuel assemblies are placed is integrated into the outer wall of the cask. The lid of a bare-fuel cask is bolted closed. In a canistered system, the assemblies are

placed inside a thin-walled canister which is then welded shut and placed inside an overpack with a bolted lid for storage or transportation (NAS 2006a).

Single Purpose Casks (SPCs) are usually of the bare-fuel category, and are licensed either for storage *or* transport, whereas Dual-Purpose Canisters (DPCs) are licensed for storage *and* transport. Casks used for transportation must be licensed under 10 CFR § 71, while casks used for storage are licensed under 10 CFR § 72. The containers are initially licensed for a 20-year period, but with Nuclear Regulatory Commission (NRC) approval, the license could be renewed for another 20 to 40 years. While casks vary in size and capacity, they generally hold up to 10-15 MTHM, which is equivalent to about 32 pressurized water reactor (PWR) assemblies or 68 boiling water reactors (BWR) assemblies (NAS 2006b). Criteria for each assembly that is loaded in dry casks, such as a maximum limit for thermal power output and burnup, are defined for each cask variety. Decay heat limits are typically lower for transportation than for storage.

In addition to the cask itself being licensed by the NRC, a waste generator must have a license to store dry casks on-site. The Spent Fuel Projects Office within the NRC offers two types of licenses for storing fuel: one that is applicable to all reactors that have a general license under 10 CFR § 50 (2008), and one that is referred to as a “site-specific” license in 10 CFR § 72.6 (2008). All away-from-reactor storage sites, referred to as Independent Spent Fuel Storage Facilities (ISFSI), must have a site-specific license (10 CFR § 72.6 (2008)). If the spent fuel is on-site, the waste generator can use a general license as long as it meets the requirements for fuel storage (10 CFR § 72 (2008)). If these conditions are met, the waste generator does not need to apply for a site-specific license (10 CFR § 72.6 (2008)).

### ***Waste Confidence Rulemaking***

The NRC has verified that current systems for storage are safe for an extended length of time (NRC 1984) . However, there is consensus among experts that the best solution for *permanently* storing the waste is deep, geologic disposal as is determined in the National Academy of Sciences *Report on the Disposal of Radioactive Waste on Land* (NAS/NRC 1957) and more recently affirmed in the *Environmental Impact Statement, Management of Commercially Generated Radioactive Waste* (DOE 1980).

In 1984, NRC held a rulemaking, referred to as the Waste Confidence Rulemaking, to determine the Commission's confidence in the safe permanent disposal of waste, the timing of when a disposal facility would be available, and whether waste could be stored safely in the meantime. The Commission concluded that sufficient repository capacity would be available by the years 2007-2009, and that waste could be stored safely, without significant environmental impacts for at least 30 years beyond the expiration of a reactor's operating license (NRC 1984).

The Waste Confidence decision was updated in 1990 to state that CSNF can be stored safely without significant environmental impact for at least 100 years, and that there is reasonable assurance that at least one deep geologic repository would be available by 2025 (NRC 1990). In 2005, in response to a petition filed by the State of Nevada, the NRC reaffirmed that there is reasonable assurance that a repository will be available by 2025, and that sufficient capacity would be made available for safely storing waste on-site or off-site without significant environmental impact for an extended period of time (NRC 2005).

Although waste can be stored safely for an extended period of time above ground, the U.S. federal government, through the Department of Energy (DOE), has been pursuing the use of a deep, geologic repository for permanent disposal of the nation's high-level nuclear waste. The availability of a repository will reduce the demand for on-site dry storage, but projections show that most commercial plants will run out of space in their pools before a repository is in operation (NAS 2006b). Thus, in coming years, dry cask storage will be necessary at many of the utility sites.

One option for storage that has been considered in conjunction with a repository, to accommodate waste in the meantime, is one or more centralized, federal storage sites. A 1984, National Research Council study recognized that attention should be given to the managerial and socioeconomic impacts of storing spent fuel above ground at reactors or at away-from-reactor sites, and that there was an incomplete body of knowledge that could help decision makers implement radioactive waste management systems. Among the findings was the need for further research to better determine the "above-ground" impacts (i.e., cost and equity) involved with various waste management strategies (NAS/NRC 1984).

The benefits and costs of federal interim storage, referred to as Monitored Retrievable Storage (MRS), were analyzed by a federally appointed commission in 1989. Results of this study indicated that a small capacity, interim storage facility would be useful, but not a large-volume one. The Commission found no safety advantage over the MRS alternative, and that no single factor favored the use of an MRS. The Commission, however, did recommend authorization of a 2,000 metric ton capacity federal emergency storage facility, and privately funded storage facility with a capacity of 5,000 metric tons.

The Commission also suggested that Congress re-examine the interim storage subject by the year 2000, noting that federal interim storage might become more economical if the repository were delayed (Radin et. al. 1989). Private consolidated interim storage sites, such as the project led by Private Fuel Storage, LLC (a consortium of eight electric utility companies) and the Skull Valley Band of Goshute Indians in Skull Valley, Utah, have also been pursued, but none are in operation today (PFS 2001). This is mostly due to political opposition from local, state, and Native American tribal governments at the sites and along transportation routes (NAS 2006a).

Today, there is talk of reconsidering consolidated interim storage, but no legislation has been passed. The rationale for this is to solve the “waste confidence” issue, to stop the litigation between DOE and the utilities resulting from DOE’s failure to take title to the waste as it was supposed to do no later than 1998, and to expedite the decommissioning of shut-down reactors so as to reduce the expenses associated with prolonged decommissioning.

However, once again, an evaluation of interim storage showed no sufficient advantages unless the repository is delayed. As noted, there are no “substantive safety or security reasons...no compelling cost savings unless Yucca Mountain is delayed”, and there is “sufficient space” at the sites where waste is currently stored (APS 2007). Whether or not consolidated interim storage will be economical in the future is not clear. After all, the 1989 study predicted that there may be economic benefit to interim storage if Yucca Mountain were delayed, but the 2007 study found no cost savings even though YM has been delayed well beyond its expected opening date of 1998. Still, the 2007 technical and programmatic assessment of consolidated storage asserts that consolidated

storage may facilitate decommissioning, as well as diminish a potential obstacle to licensing new nuclear power plants (APS 2007).

### ***Reprocessing***

In addition to direct geologic disposal, the federal government (through the DOE) and some commercial entities are considering reprocessing spent nuclear fuel. DOE has been researching reprocessing technologies under its Advanced Fuel Cycle Initiative for several years, and recently the agency proposed a fairly aggressive timeline for commercial-scale production of reprocessing facilities under the Global Nuclear Energy Program (GNEP) (DOE 2006c). Development of such facilities would decrease the volume and radiotoxicity of the final high-level waste product, but there would still be a need for a geologic repository to dispose of the reprocessed waste. Thus, even though there are alternative options for managing the waste in the interim, the U.S. government is actively pursuing deep geologic disposition, with the option for retrieving the waste, as a way to dispose of the waste.

## **Yucca Mountain Legislative History**

### ***Nuclear Waste Policy Act***

The NWPA tasked DOE with siting, building, and operating one or more deep geologic repositories for the country's spent nuclear fuel and high-level nuclear waste (42 USC § 10101 (2008)). Section 304 established the Office of Civilian Radioactive Waste

Management as a part of DOE and a process was developed for investigating and approving potential repository sites. The Nuclear Waste Fund was also established in §302. Waste generators pay into the Nuclear Waste Fund at the rate of a mil per kWhr in exchange for DOE taking title to the waste.

In 1984, DOE issued draft environmental impact statements for nine potential repository sites it had identified (DOE 2002). The sites, comprised of a variety of geologic formations and geographical locations, were: (1) Hanford, Washington, (2) Yucca Mountain, Nevada, (3) Deaf Smith County, Texas, (4) Davis Canyon, Utah, (5) Richton Dome, Mississippi, (6) Cypress Creek Dome, Mississippi, (7) Lavender Canyon, Utah, (8) Vachene Dome, Louisiana, and (9) Swisher Site, Texas (DOE 2002).

In 1986, Secretary of Energy Herrington nominated five of the nine sites (1-5). Three of those sites (Hanford, WA, Yucca Mountain, NV, and Deaf Smith County, TX) were recommended to President Reagan, who approved a full characterization of the three sites (Abraham 2002). In 1987, Congress amended the NWPA and mandated that DOE focus efforts exclusively on Yucca Mountain, NV (YM) (NWPA § 160(a), 42 USC § 10101 (2008)). In February, 2002 Secretary Abraham recommended the site to President George W. Bush, after which he approved the site (Abraham 2002). Although the State of Nevada vetoed the President's approval, Congress overrode the veto. The final legislative vote confirming the suitability of a repository at YM was cast on July 9, 2002. Subsequently, President Bush signed House Joint Resolution 87, approving the site (H.J. Res. 87, 107<sup>th</sup> Cong. (2002)).

### ***Licensing Process***

The licensing of YM is carried out in three separate phases: authorization for construction, approval of a license to receive the waste, and then an approval of an amendment to the license in order to decommission and permanently close the disposal facility (42 USC 10101 § 405 (2008)). The procedures for licensing (i.e., initial acceptance review, extensive technical review, opportunity for public comment, and public hearings) remain the same for each phase of the process. For example, before DOE can begin constructing the repository, it must be granted authorization for construction by the NRC. DOE has stated that it expects to submit a License Application (LA) sometime in 2008 (Sproat 2007). The primary technical document in the LA is a safety analysis report, which must demonstrate that the repository will be built and operated to adequately protect public and worker health and safety, as well as to be designed to preserve the local environment. Once submitted, NRC will determine if the application is suitable for performing a detailed technical review. If the LA is deemed sufficiently complete, NRC will docket the application and commence an extensive technical review. The technical review will determine if the repository will meet the regulations in 10 CFR § 63.

During this time, there will be opportunities for affected parties to file contentions having to do with the repository and to participate in hearings. Hearings will be conducted by a panel appointed by NRC, referred to as the Atomic Safety and Licensing Board. After NRC completes its review, and the Board finishes processing contentions, hearings will take place. After all contentions and responses have been heard, the Board will issue its decision regarding construction. If the decision is favorable, and is not

overturned by the NRC Commissioners or the appellate court, construction can begin. Once construction of the repository is nearly complete, the second phase of licensing YM will begin with DOE's request for a license to receive waste. Because the license review and hearings are expected to take several years, the earliest estimate for opening the repository is 2017 (Williams 2006).

### ***Standard Contract***

The NWPA authorized the Secretary of Energy to develop an agreement with the owners and generators of spent fuel (10 CFR § 961 (2008)). The guidelines set forth in the *Standard Contract* for the acquisition of spent nuclear fuel and its transportation to the repository have potential to impact repository design. The *Standard Contract* requires spent fuel to be at least five years old to qualify to be sent to YM, but is not as specific about the particular timeline of shipments.

For every year after the repository starts accepting waste, there is a specified allocation, measured in metric tons, which each waste generator, called "Purchaser", is expected to send. The term Purchaser is used because spent fuel generators have been purchasing the services of DOE by paying into the Nuclear Waste Fund. A single Purchaser may own one or more reactor facilities, depending on the size of the Purchaser's corporation. Allocations given to each waste generator are detailed in the *Acceptance Priority Ranking (APR) and Annual Capacity Report (ACR)* (DOE 2004). The queuing order is based on the date spent nuclear fuel was permanently discharged, giving priority to the oldest spent nuclear fuel on an industry-wide basis. This order is

combined with the annual rate of acceptance for YM to calculate yearly allocations for each Purchaser (DOE 2004).

Allocations in the *APR/ACR Report* are not contractually binding on either DOE or the Purchasers. Instead, they are meant to assist Purchasers' planning and submittal of Delivery Commitment Schedules (DCS), which specify what fuel they intend to send and the delivery dates for shipments. Legal requirements of the DCS allow for negotiations between Purchasers and DOE, as outlined in Article V of the *Standard Contract*, until six months before the date of delivery. Purchasers are also permitted to *exchange* allocations with other Purchasers, as long as DOE approves of the exchange (10 CFR § 961 (2008))

Unfortunately, because the allocations for waste shipments do not obligate Purchasers to send their oldest fuel first, and there is opportunity for altering schedules up to six months before the delivery date, it is difficult for DOE to accurately predict the age of the fuel that will be sent at the time when it is designing the repository. Uncertainty regarding the age of fuel assemblies that are shipped is important to the thermal management strategy for repository design during the "pre-closure" phase of Yucca Mountain, the operational phase of the repository during which waste is transported to and emplaced in the repository, but kept retrievable. Post-closure involves repository behavior after the emplacement drifts have been closed.

### **Yucca Mountain Repository Design History**

The Final Environmental Impact Statement (FEIS) for YM discusses design alternatives regarding a number of factors for pre-closure operations and the layout of the

repository, including packaging, transportation, ventilation, and emplacement drift spacing. Of the designs, two packaging alternatives for pre-closure were considered by DOE in the FEIS: (1) the waste would be mostly canistered in DPCs and (2) the waste would be mostly uncanistered in bare-fuel transportation casks. In both alternatives, DOE would have had to handle *all* assemblies as bare-fuel at the YM surface facilities in order to load them into final waste packages since DPCs are not designed for long-term disposal (DOE 2002).

In order to reduce the number of bare-fuel handlings required at YM, DOE announced a change in design, requiring the operators of facilities in possession of spent nuclear fuel to use a Transport, Aging and Disposal (TAD) canister to transport CSNF to YM (DOE 2006b). Even with the TAD design, spent fuel assemblies arriving at YM in DPCs will need to be repackaged into TADs.

### ***Licensing and Design of the TAD***

Since the TAD will be used in a variety of applications, it will be governed by several regulations. For example, a TAD loaded at a nuclear power plant will be governed by 10 CFR § 50. If the TAD is placed in an ISFSI for interim storage, it will be regulated under 10 CFR § 72. A TAD placed in a certified overpack and transported is licensed under 10 CFR § 71, while a TAD placed in an overpack for aging at YM will fall under 10 CFR § 63. To ensure that the TAD is developed according to the requirements of 10 CFR § 63, DOE, as opposed to the vendors, specifies the design of the canister. This is important because it implies that DOE has considerable influence over the design of the TAD. The design specifications for the TAD, released by DOE in 2007, are intended to guide

vendors as they prepare license applications for the TAD under 10 CFR § 71 (transportation) and 10 CFR § 72 (storage) (Shah 2006).

The design specifications released by DOE do not stipulate a specific thermal limit for transportation or storage, but rather provide cladding temperature determination for total thermal outputs of 11.8 kW, 18 kW or 25 kW. Once the TAD is licensed under 10 CFR § 71 and § 72, utilities can begin using it for storage and transportation. DOE will submit a license application under 10 CFR § 63, which will describe the use of the TAD in overall repository design. NRC will determine if the TAD is important to safety in its review of the LA. Specifically, the agency will determine if there are attributes of the TAD that are important to waste isolation, and also if there are attributes of the design that have a detrimental effect on post-closure performance (Shah 2006).

### ***Motivation for the TAD Decision***

The decision to use the TAD is motivated by the fact that utilities have more experience in handling and packaging CSNF, and that the number of handlings of bare-fuel assemblies at YM would be reduced considerably. In preliminary dose calculations for the surface facility where assemblies would have been transferred (Dry Transfer Facility), the ALARA<sup>1</sup> goal of 5 mSv (500 mrem) per year for normal operations was not met for the cask waste/receipt operator and the health physics worker. Specifically, cask waste/receipt operators and health physics technicians were estimated to receive a total effective dose equivalent (TEDE) of 18 mSv (1800 mrem) per year, and 8 mSv (800

---

<sup>1</sup> All worker and public exposures to ionizing radiation must be kept as low as reasonably achievable (ALARA) (10 CFR § 20.0011(2008))

mrem) per year, respectively, due to direct radiation from contained sources (BSAIC 2004a).

Furthermore, because of the large number of assembly handlings, the drop of an assembly had a rate of 0.5 events/yr and 9.7 expected drops<sup>2</sup> over the 50-year pre-closure period of operations (BSAIC 2005a). The consequence analysis conservatively assumed that 100 percent of the fuel rod cladding is breached in the event of a drop, and that each CSNF assembly would undergo four (4) transfers. The expected aggregated dose from normal operations and the drop events that were expected to occur at least once during the 50-year pre-closure period was 0.022 Sv (2.2 rem)/yr (BSAIC 2005c). This dose is within the regulatory limit of 0.05 Sv (5 rem), but the design was reconsidered to reduce the number of assembly transfers.

Usage of the TAD will lower the cost of DOE facilities, reduce low-level waste production, decrease risk of worker dose at DOE facilities, and simplify DOE operations (Kouts 2006b). Still, there is uncertainty as to the ultimate impact of the TAD decision since the canister is yet to be commercially deployed and adopted for use by the utilities. Some speculate that the advantages may not counterbalance the operational inefficiencies of a smaller and potentially costlier container. After all, a similar concept involving a multi-purpose canister was proposed in 1992 and then dismissed in 1995 because it was considered too costly (DOE 1996). The cost of the surface facilities at the repository may

---

<sup>2</sup> Based on 221,000 total assemblies over pre-closure, at a maximum rate of 12,628 assemblies/year and a drop rate of  $10^{-5}$  drops per transfer. A conservative factor of 1.1 is included and each assembly is assumed to be transferred 2 times.

be lowered, but the TAD canister itself is expected to be more expensive than the casks currently in use.<sup>3</sup>

Assuming DOE does not pay for the TAD, using it would impose additional cost on the utilities. Under the *Standard Contract*, paying for on-site storage remains the responsibility of the utilities until DOE takes title to the waste (10 CFR § 961 (2008)). Contracts would need to be renegotiated if DOE is to cover the costs of the TAD. Renegotiations may be complicated since several utilities are currently in litigation with DOE over its failure to take title to the waste by the 1998 deadline. As of 2006, 60 cases were still pending before the courts (NAS 2006b). Even though the perspectives of the utilities vary, the Nuclear Energy Institute (NEI), an industry policy organization, has expressed that there is a general desire to facilitate success of the TAD concept since it is viewed as pivotal to assuring progress on Yucca Mountain (McCullum 2006).

## **Problem Statement**

### ***Safety Considerations***

While use of the TAD would most likely reduce dose risk for workers at YM, the extent that dose risk is reduced for DOE workers depends heavily on the percentage of fuel that arrives in TADs. Dose risk is expected to decrease for YM workers with the use of the TAD because the number of uncanistered CSNF assembly crane lifts is reduced.

---

<sup>3</sup> Personal communication with Adam Levin, Director Spent Fuel and Decommissioning Strategy, Exelon Generation Company. December, 2006.

Assuming that 90% of spent fuel arrives in TADs, the number of lifts is reduced by a factor of 20 (Tooker and Dunn 2006). Utilities will not desire to repackage the waste that is already in DPCs because it would expose their workers to additional risk. The safety case and overall effectiveness of the TAD rests with the assumption that 90% of the 63,000 metric tons of CSNF to be emplaced in YM will arrive in TADs (DOE 2006d). As stated, approximately 15% of CSNF is already in on-site dry cask storage, either in DPCs or SPCs.

### ***Surface Facility Throughput Considerations***

Use of the TAD also creates a potential problem in terms of surface facility throughput. Before any final disposal package, referred to as a Waste Package (WP), can be emplaced in YM, its total thermal power output (kW) must fall below a specified thermal emplacement limit. The thermal emplacement limit for each WP is defined as 11.8 kW in YM design documents, but ongoing studies are exploring the possibility of easing this constraint up to 18 kW, or even higher (BSAIC 2005d). Any packages not meeting the specified limit must be stored above ground at YM until the contents cool to a value below the thermal emplacement limit.

The Nuclear Waste Technical Review Board (NWTRB) has expressed concern that the decision to use the TAD canister may impact the thermal management strategy of pre-closure operations, mainly due to the fact that the utilities, as opposed to DOE, will now decide how to blend fuel assemblies into the *final* disposition canisters. The utilities' discretion to blend fuel to their preferences greatly reduces DOE's control over the

thermal power outputs of the packages as they are being prepared for emplacement in the mountain (NWTRB 2006).

There are potential inefficiencies in the existing method for allocating shipments that stem from use of the TAD. The existing method, as stipulated in the *Standard Contract*, was developed prior to the TAD decision, and therefore does not adequately consider the ability of the utilities to co-mingle hot and cold assemblies according to DOE's thermal management strategy. This critical decision introduces uncertainty regarding the thermal power output of the WPs, causing potential for a highly variable need for aging at YM.

The amount of waste aging above ground at YM is likely to be a contentious issue during the LA hearing process. The Nuclear Waste Policy Act, as amended, prohibits selecting Nevada as the site of a Monitored Retrievable Storage (MRS) facility. The NWPA §145(g) states that, "no monitored retrievable storage facility authorized pursuant to §142(b) may be constructed in the State of Nevada." If the aging pad falls under the legal definition of an MRS, then it could be argued that DOE, in designating Yucca Mountain as the site for it, has failed to follow the site selection criteria for a proposed MRS (NWPA, as amended, §145(g) -§142(b) , 42 USC § 10101 (2008)).

If the aging pad does not fall under the definition of an MRS, it could be argued that it is an ISFSI. ISFISI's, as defined under 10 CFR § 72.3, require a stand-alone Environmental Impact Statement (EIS) for construction. In this case, DOE's failure to provide an EIS for the aging pad could be construed as neglecting the requirements of the National Environmental Policy Act of 1969 (42 USC § 4332(c) (2008); 40 CFR §1508.27 (2008)).

The aging pad could be interpreted as part of geologic repository operations, causing it to be governed under 10 CFR § 63. The NWPA § 2(18) defines "repository" as including incidental areas for "handling activities" (42 USC § 10101 (2008)). Long-term aging of the waste may or may not be considered a "handling activity". This legal question is still to be determined. The critical determination that will be played out in the hearings is whether cooling of the spent fuel on a large scale is integral to the operation of the repository.

Ideally, through careful planning, DOE could design the surface buildings such that operations of YM are facilitated and the needs of the waste generators are met in a safe and efficient manner. While DOE is refining its studies to accomplish such objectives, the approaching LA submittal may limit DOE in terms of time and resource constraints. Analyses may be influenced by the tendency to grandfather past studies, assumptions, and models in long-lived, large-scale projects. There is potential benefit from a renewed approach to analyzing the impact on process flow and storage requirements of pre-closure design and operating decisions. This brings motivation for an independent analysis of various pre-closure scenarios that may improve operations with regard to surface facility aging and throughput.

### **Research Objectives**

This research seeks to compare relative "operational performance" of the pre-closure waste management system under various design and implementation approaches regarding utility selection of assemblies for dry storage loading, transportation, aging, and emplacement in relation to the proposed geologic repository for high-level waste at

Yucca Mountain, Nevada. The term operational performance is specific to this dissertation and should not be misinterpreted as the way “pre-closure performance objectives” are defined in 10 CFR § 63.111.

In general, desired operational performance is defined as an approximately steady-rate flow of waste from utility sites to the repository with an appropriate thermal output for emplacement during operating years. More specifically, desired operational performance of the waste management system includes: reducing dry storage requirements at the utility reactor sites, improving the efficiency of the transportation movements, reducing the number of shipment origin locations per year, meeting the receipt-rate goals for YM, and reducing the number of material handlings at the surface facilities. A “scenarios” approach is applied that focuses on key uncertainties, providing a framework for anticipating multiple pre-closure outcomes.

Therefore, objectives of this research are to explore the following:

- What is the relationship between the thermal characteristics of the waste packages and various design and operating conditions?
- Which scenarios result in adverse conditions, e.g., delays in waste acceptance, increased aging requirements, etc.?
- Which scenarios result in improved operational performance, e.g., more efficient packaging and fewer handlings of spent fuel over time?

## **Organization and Content of Dissertation**

Chapters 2, 3, and 4 of this dissertation consist of a series of research papers. Each of these papers either has been or soon will be submitted to a refereed journal for

publication consideration. Although the papers consecutively build upon each other, they can be read as stand-alone documents. For this reason, portions of the background material may be replicated in the respective introduction sections of each chapter. This format may burden the more knowledgeable reader with repeated introductory material, but it may also be useful to readers that prefer to review chapters as stand-alone papers. An overview of the contents of each chapter is provided in the following paragraphs.

Chapter 2 introduces the framework for characterizing YM pre-closure as an integrated system comprised of input assumptions and quantifiable, performance metrics as outputs. The paper describes the modeling tool that was developed for this research and its application to identify scenarios that might improve overall performance. A total of 81 scenarios were explored in this application (see Appendix F for resulting data). These included a method for trading allocations, prioritizing the allocations based on least remaining capacity in the spent nuclear fuel pools at the utility sites. Results indicate that this type of prioritization reduces demands for dry storage at the waste generation sites without adversely impacting the amount of aging required under the youngest fuel first scenarios. Future research is suggested to account for surface facility safety implications and throughput constraints associated with various scenarios.

Chapter 3 and Chapter 4 are a two part series that employ the model to generate waste streams for 162 pre-closure scenarios (see Appendix F for resulting data). The scenarios are characterized with similar parameters to those introduced in Chapter 2, except utility trading of allocations based on least remaining capacity is not carried forward so that results for the expected frequency of a drop and surface facility throughput can be more readily compared with those in DOE safety and throughput design documents.

Allocation trading is still permitted in some scenarios, but only that which is based on age. New functional capability is incorporated into the model that allows for prioritization of waste removal from the dry storage pads at waste generation sites before the spent nuclear fuel pools. The enhanced model is also capable of prioritizing shipments of DPCs before TADs or vice versa when removing waste from the dry storage pads at the generation sites, since utilities that are in possession of both DPCs and TADs will have the opportunity to make such a decision, and it is not obvious how they will behave.

Chapter 3 focuses on the safety implications specific to material handlings of various waste streams by accounting for the expected number of transfers in each scenario. Comparisons are made of the resulting frequency of dropping a TAD, DPC, or bare-fuel assembly to the estimated frequency in DOE's *Preliminary Hazards Analysis*. Results show that DOE's estimate for the frequency of a drop is within the range of likely frequencies but does not conservatively bound the generated results. A probabilistic approach for estimating the frequency of drop events is recommended that could help communicate the risk and contribute to pre-closure analyses.

Chapter 4 focuses on how waste stream variations affect surface facility throughput, namely the rate at which packages are prepared for aging or emplacement in the surface facilities at YM. Annual demand at the surface facilities is estimated under each of the 162 scenarios by applying a simplified process flow scheme to surface operations. The basis for surface facility design and throughput requirements is reviewed by evaluating the current design subject to various waste stream scenarios. The surface design goals of the system are evaluated as to the capability to meet annual demand. Results indicate that

the capacity for the Wet Handling Facility (WHF) may need to be increased in order to efficiently process waste that does not arrive in TADs, unless DOE is able to effectively limit the number of Dual-Purpose canisters and bare-fuel cask shipments. A critique of the current design reveals that there may be benefit derived from systematically accounting for the overlap of transfer capability in the Canister Receipt and Closure Facility (CRCF) and the Receipt Facility (RF). An alternative set of throughput requirements for the surface facilities is proposed.

Chapter 5 provides a summary of major findings from this research. It also discusses some of the broader insights of managing the design of long-lived and large-scale engineering projects such as YM. Additionally, recommendations for future research using the modeling tool that was developed are suggested.

## CHAPTER II

### EVALUATING PRE-CLOSURE OPERATING STRATEGIES

#### **Abstract**

This chapter describes the development and preliminary use of an integrated model to explore the impact of design parameters and operational decisions on storage and transportation aspects of pre-closure activity period for the potential repository at Yucca Mountain (YM), NV. The model provides an opportunity to perform analyses of various YM pre-closure “scenarios”. Storage and transportation aspects of the pre-closure system are evaluated with the goal of identifying important design parameters and understanding system interactions, thereby providing a tool to recognize trade-offs and dependencies between storage demands at the waste generation sites and the repository.

This application of the model explores changes in assumptions regarding the following parameters: (1) year the TAD becomes available, (2) year that YM opens, (3) thermal limit for emplacement, (4) thermal limit for transportation, (5) utility approaches to selecting assemblies for dry storage loading, and (6) capacity of Yucca Mountain.

The response variables measured are the total counts of: (1) dry storage containers loaded due to lack of capacity in the spent nuclear fuel pools, (2) TADs that could potentially be loaded before YM opens assuming utilities begin using the TAD as soon as it is commercially available, (3) pools making shipments to YM each year, (4) years the Aging Facility at YM is required, and (5) containers in the Aging Facility each year.

Analysis results indicate that allowing utilities to trade allocations, prioritizing the trading based on least remaining capacity in the spent nuclear fuel pools, will reduce dry storage demands at the utility sites, decrease the number of pools making shipments each year, and increase the efficiency of the transportation system. This type of prioritization for allocations can provide these improvements without adversely impacting the required aging above ground at YM in the case that younger fuel is sent first. Consequently, there may be incentive for utilities to negotiate the trading of allocations if they wish to reduce their expected dry storage demands. Results also indicate that DOE could reduce above aging at YM by enforcing a lower transportation limit or relaxing the emplacement limit.

## **Introduction**

### ***Yucca Mountain Waste Management System***

For several decades, the U.S. Department of Energy (DOE) has pursued the use of an underground geologic repository at Yucca Mountain (YM), Nevada for permanent disposal of the nation's spent fuel and high-level nuclear waste. The YM project consists of two temporal phases: (1) pre-closure, which may last as long as 300 years of repository operation, and (2) post-closure, which is associated with containment of radionuclides potentially out to one-million years (NAS 1995). Pre-closure operations can be thought of as a "waste management system" defined as all components, facilities, and activities that collectively manage the waste as it is packaged at the generation sites, transported to

the repository, received and processed at the YM surface facilities, and emplaced in the repository.

In the following discussion of the waste management system, the terms canister, cask, container, and waste package will hold specific meanings. Canister is defined as a metal vessel for holding spent nuclear fuel assemblies. A transport, aging, and disposal canister (TAD) is suitable for storage when within an aging overpack or shipping when within a transportation overpack. It is also suitable for disposal when within a corrosion-resistant disposal overpack, in which case it is referred to as a Waste Package (WP). A Dual-Purpose canister (DPC) is suitable for storage when within an aging overpack or shipping when within a transportation overpack, but is not considered to be suitable for disposal. Transportation cask is defined as a vessel for transportation that holds either bare-fuel assemblies or a canister containing bare-fuel assemblies. Dry storage container is defined as a vessel suitable for dry storage of the spent nuclear fuel. A dry storage container may be a TAD in an aging overpack, a DPC within an aging overpack, or a single-purpose container that holds bare-fuel assemblies appropriate for storage but not transportation. The author will refer to a TAD or a DPC within a transportation or aging overpack as simply TAD or DPC when it is clear that the TAD or DPC is being shipped or stored.

Since YM is still in the planning stages, there are many feasible “scenarios” comprised of design and operating assumptions for the waste management system. In the pre-closure phase, temperature is controlled through a thermal management strategy based on the thermal power output (kW) of the fuel at time of emplacement and ventilation of the emplacement drifts.

While much attention has been devoted to subsurface repository behavior, it is becoming clear that additional analysis is needed to address emerging pre-closure matters that are inextricably linked to the thermal power output (kW) of the fuel at time of emplacement, such as waste shipment transportation schedules, dry storage loading practices, and above-ground dry storage capability at YM. The thermal management strategy for the repository rests with the flexibility to select waste packages with the appropriate thermal power output, from those on the surface aging pad, in order to maintain a midpillar region below the boiling point of water (DOE 2002).

The thermal characteristics of the inventory above ground at YM are related to pre-closure operating decisions for package loading and waste acceptance. Numerous studies have been conducted concerning waste emplacement, waste package sequencing and ventilation to achieve the thermal management goals (Ryman 2001; Yang 1999). However, a good understanding of the relationship between thermal requirements for waste emplacement and subsurface and surface storage needs, both above ground at YM and at the waste generation sites, during pre-closure operations has not been demonstrated. Consequently, there is a need for a better understanding of how pre-closure operations and design variables impact these aspects of the pre-closure system.

### ***Thermal Management Strategy***

In order to ensure that the repository behaves as expected in the post-closure environment, criteria for the thermal loading of the repository have been established. There are four maximum thermal criteria: (1) 350°C cladding of the WP, (2) 300°C on the surface of the WP, (3) 200°C on the surface of the drift wall, and (4) 96°C in the

pillars between the drifts. The main factors affecting the initial thermal loading of the repository are: (1) characteristics of spent nuclear fuel such as burnup, enrichment and years out-of-reactor, (2) physical properties and layout of the repository, and (3) operational timing - such as ventilation duration, as well as waste package loading, sequencing and spacing (DOE 2002). Assumptions regarding these factors are fed into thermal hydrological models characterizing the flow of heat, moisture and air during pre-closure and post-closure in the emplacement drift (BSAIC 2005b).

One critical assumption regarding operational timing is the aggregate thermal power of the consecutively placed waste packages averaged over some distance within the repository drifts, referred to as the average thermal line-load. The average line-load at emplacement, currently defined as 1.45 kW, is based on an idealized sequence of seven (7) WPs within the drifts (BSAIC 2005b). This sequence alternates WPs that are expected to have hotter initial heat loads with those that are expected to be cooler upon emplacement in order to control the average thermal load over some distance.

The initial thermal power load is derived from the thermal power given off by six (6) WPs and one-half of the thermal power output of the WP at either end (Table 1). (The designation of one-half of each package at either end should not be misinterpreted as a half-loaded package; the packages are fully loaded, but only half of the thermal load is attributed to the single sequence). The *Monitored Geologic Repository Project Description Document* states there should be a 10 cm spacing between WPs and limits the maximum linear heat load, averaged over a fully loaded emplacement drift at the time of completion of loading an entire drift, to 1.5 kW/m (DOE 2000). Applying a spacing of 0.1 m between each WP in Table 1 causes the total length of the WP sequence to be

approximately 35 meters. Summing the thermal output and dividing by the total WP sequence length results in an average line-load of 1.45 kW/m.

The fuel assemblies in each WP in this sequence are assumed to have cooled for about 25 years out of the reactor at time of emplacement (BSAIC 2005b). The thermal energies at time of emplacement corresponding to this sequence of WPs are used to produce an average thermal decay curve that can be used in models characterizing repository heat load (BSAIC 2005b).

The current thermal management strategy for the repository requires each WP to be below a thermal limit of 11.8 kW, which corresponds to the maximum initial thermal power output required at the time it is emplaced (see Table 1). On-going studies are exploring potential higher values for the emplacement limit (BSAIC 2005d). Above-ground aging at YM is necessary because DOE is unable to ensure that spent fuel arriving at the repository will be cool enough such that it can be directly emplaced. However, if spent fuel could be at or near the emplacement limit upon arrival, aging of a large portion of the fuel would not need to take place *at the repository site*.

DOE has more control over some of the factors that affect thermal loading of the repository (e.g., duration of ventilation) than others (e.g., rock properties). However, it is debatable how much control DOE will exhibit over the age of the fuel when it arrives, and which individual fuel assemblies will be blended into the final waste packages. This apparent lack of control may be a result of the method used to establish waste shipping order and the decision to use a multi-purpose canister for transport, aging (storage), and disposal (TAD).

Table 1

Line Load Waste Package Sequence

| WP Design             | Approximate thermal power output per WP (kW) |
|-----------------------|--|
| ½ 21 PWR <sup>a</sup> | 5.76   |
| 5 HLW Long            | 0.99   |
| 21 PWR                | 11.8   |
| 44 BWR                | 7.38   |
| 44 BWR                | 7.10   |
| 5 HLW Short           | 2.98   |
| 21 PWR                | 11.5   |

<sup>a</sup>one-half of the total estimated thermal power output for these WPs are counted as contributing to the waste package sequence

The *Standard Contract* between DOE and the waste generators establishes the order in which DOE will accept spent fuel from the utilities, referred to as “Purchasers” (10 CFR § 961.3 (2008)). The Act specifies that the order be based on the order in which fuel was discharged, but does not specify the actual age of the spent fuel that is to be shipped (10 CFR § 961.11 Article V (2008)). Prior to the TAD concept, spent fuel assemblies were to arrive at YM in transportation casks carrying uncanistered spent fuel assemblies or DPCs. Since assemblies were to be repackaged at YM prior to this decision, the combination of assemblies in a single shipment from any given Purchaser was less important. There is a need to explore potential impacts resulting from the decision to use the TAD, but DOE’s existing analysis tools may be limited in accomplishing this task as described in the following section.

### ***Previous Research***

DOE is currently using and refining a simulation model for assessing pre-closure risk called the Total System Model (TSM). This model was developed by DOE to simulate alternative scenarios of waste management system design and operation. The purpose of TSM is to enable DOE to understand how alternative operational scenarios impact system throughput, cost, and potential dose. TSM is viewed as having considerable potential for more robust analysis (Kouts 2006a).

Unfortunately, DOE may be limited in its ability to fully utilize TSM in addressing important design and operational considerations. This may be in part due to time constraints as well as constraints imposed by the model construct. TSM uses “grandfathered” logic and databases, as well as a number of disparate software programs.

The portion of the model that develops the schedule for waste shipments, called the Total System Model Pre-Processor (TSMPP), is separate from the simulation of transportation and surface facility operation (BSAIC 2004b).

TSMPP is based on previous methods in CRWMS (Civilian Radioactive Waste Management System) Analysis and Logistics Visually Interactive (CALVIN) Model, and thus retains some of the structures and functions no longer necessary for present purposes. While the unused structures or functions most likely do not hinder the accuracy of analyses, they may decrease the efficiency, transparency, or ease of use of the tool itself (BSAIC 2004b).

The output of TSMPP is fed into TSM as a static spreadsheet, impeding the incorporation of feedback from TSM to TSMPP. This structure does not allow for parameters in TSM regarding surface facility activity to affect the shipment schedule. The disconnect between TSMPP and TSM decreases the capability to recognize potential improvements in latter parts of the shipment schedule that could be gained from understanding the dynamics in storage demands at the utility sites and at YM due to decisions regarding packaging and transportation in earlier portions of the shipment schedule (BSAIC 2004b).

DOE's analysis of the pre-closure waste management system using TSM is isolated from its subsurface repository and emplacement drift modeling. For assessing repository performance, DOE is using a tool called Total System Performance Assessment (TSPA), developed with the GoldSim software platform. The pre-closure scenarios that are explored by DOE are somewhat restricted by the parameter values that are a part of the TSPA modeling assumptions. The time constraints imposed in order to complete the

License Application (LA) may require that certain parameter assumptions in TSPA be static. Maximum thermal loading of waste packages before emplacement (currently limited to 11.8 kW) might be one of the fixed design criteria.

Potential pre-closure scenarios should be evaluated in a way that recognizes tradeoffs between the preferences of waste generators and the desired characteristics for repository operation. Use of an integrated approach that reveals trade-offs and dependencies can accomplish this objective. In its 2005 Report to Congress, the Nuclear Waste Technical Review Board (NWTRB) highlighted the importance of a pre-closure operations model that includes all components of the waste management system, including waste acceptance, transportation, aging, and emplacement. While, the NWTRB recognizes the potential for the TAD to improve facility operations at YM, the TAD also introduces challenges that must be overcome before its potential benefit can be fully realized. Specifically, the Board pointed to the timing of the availability of the TAD for dry storage use at the utility sites, as well as the relationship between the TAD and the thermal management strategy, including the amount of aging required at the surface of the repository (NWTRB 2006).

### **Research Objectives**

In response to these needs, the author has developed an integrated tool, designed around the latest critical TAD decision. The model can be used to better understand operational parameters that affect the timing and thermal characteristics of TADs arriving at the repository. Results from a previous analysis highlighted the potential inefficiencies of the allocation queue that stem from the TAD concept (Spradley, Abkowitz and Clarke

2008; Appendix D). That finding provided motivation to explore possible benefits achieved through additional variations in the allocation queue. The reader is referred to this study for a description of the tool and initial findings. The remainder of this chapter will provide a brief overview of the model, additional functionality incorporated since its prior application, and results stemming from further analyses.

The specific objectives of this analysis are to:

- Illustrate the importance of the timing of commercial availability of the TAD with regard to the number of TADs that may need to be loaded with fuel that will already be in dry storage at the utility sites.
- Identify the impact of thermal limits for transportation and emplacement on the amount of waste that is required to be aged at YM.
- Analyze the effect of allowing utilities to trade allocations based on least remaining capacity in their spent nuclear fuel pools on: storage requirements at the utility sites, efficiency of the use of dedicated train capacity, average number of pools from which waste is shipped each year, and aging requirements at YM.

### **Analysis Methodology**

An overview of the model that was developed for this research is provided in this section. For a more complete description of the model, see Appendix A.

### *Software Resources*

The model for this research was developed using GoldSim, a commercially available simulation software package that incorporates optimization and sensitivity analysis functions. GoldSim is appropriate for this type of analysis because of its capability to simulate both discrete and continuous processes simultaneously. This ability allows the incorporation of shipment schedules that are triggered by real-time characteristics of the system (Goldsim 2007).

Each commercial reactor is implemented as a set of elements that model characteristics of CSNF inventories as well as reactor discharge and loading schedules. GoldSim Array Elements are defined to track which assemblies have been placed in dry storage containers and which are remaining in the pool. The Allocator Element within GoldSim is utilized to create a dynamic shipment schedule, allocating shipments from waste generation facilities based on pre-defined priorities, such as the age of the fuel or the available capacity for storage in the spent nuclear fuel pools at the waste generation sites. Shipments to the repository are triggered by the Allocator Element within GoldSim and are modeled as discrete transactions on a yearly basis.

GoldSim Elements tracking the cumulative amount of waste above and below the thermal emplacement limit are also defined. In this sense, the model is an integration of the aforementioned TSMPP and TSM capabilities. The simulation in this analysis is carried out for the emplacement phase of the pre-closure period to gain a better understanding of repository surface operations. GoldSim is not used in this application to calculate temperatures associated with the subsurface of the repository (e.g., midpillar,

cladding, waste package, and drift wall), which is considered outside the scope of this analysis.

### ***Available Data***

Since approximately 90%, or 63,000 metric tons uranium (MTHM), of 70,000 MTHM destined for Yucca Mountain will be commercial spent nuclear fuel (CSNF) as opposed to DOE SNF or high-level waste, this analysis was limited to commercial spent nuclear fuel. The DOE SNF and HLW canisters will likely have a lower thermal energy output and are therefore not expected to be a driving factor in the amount of aging that will need to take place above ground. CSNF inventory data was taken from the RW-859 2002 Database, supplied by the Energy Information Administration (EIA 2002). The final burnup (GW-d/MTHM), initial enrichment (in weight percent), mass at initial loading (kg of uranium), and date of discharge were available for each assembly that has been permanently discharged from every reactor (EIA 2002).

Projections of fuel discharges are estimated assuming trends in burnup and license renewals. All currently operating reactors that have not yet received license extensions are granted 20-year extensions so that they are operated for a total of 60 years. An annual fractional increase in burnup of 0.01 is assumed until a maximum of 57 GWd/MTHM or 62 GWd/MTHM is reached for pressurized water reactors and boiling water reactors, respectively (BSAIC 2002). Thermal values are calculated using tables (Appendix E) developed by DOE that provide the thermal output for final burnup, initial enrichment, and years out of reactor. Thermal powers are interpolated linearly between burnup and enrichment values and logarithmically between years out-of-reactor (BSAIC 1999).

### *System Constraints*

The Yucca Mountain pre-closure waste management system is defined by a set of constraints that determine how the waste is packaged at the utilities, transported, and processed at the surface facilities. In addition to rules that govern the flow of waste after the repository has opened, assumptions are also applied regarding how the facilities manage their pool inventories before YM begins to accept waste. Fig. 1 describes the model logic for packaging waste into dry storage before the repository opens.

The simulation begins in the year 2002 since that is the year the available inventory was updated. From the year 2002 until the repository opens, each year the SNF pools are checked to see if they have reached the licensed capacity provided in the EIA database. It is recognized that although it is not legally required, it is common practice for most facilities to leave a full core reserve in their pools. Therefore, results are expected to err on the side of estimating less containers being loaded than may actually be loaded. Facilities load dry storage only when demand for their pools exceeds capacity. Assemblies removed from the pool are loaded into DPCs until the TAD is available for use. Before the TAD is available, it is anticipated that facilities will load fuel into a generic container that is the same size as the TAD (21-PWR or 44-BWR assemblies).

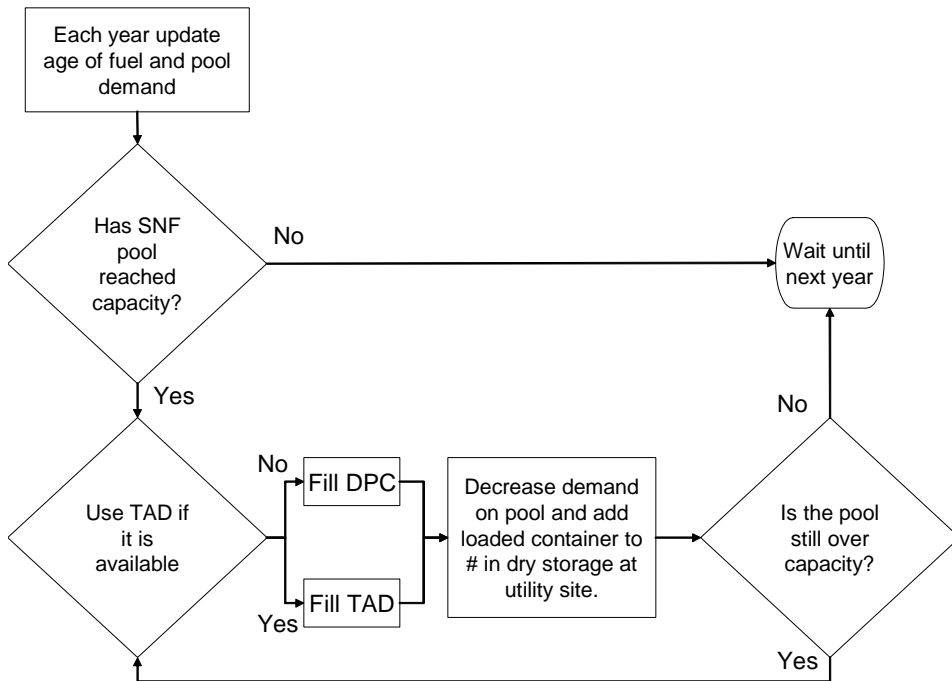

Fig. 1. Logic flow diagram for packaging waste into dry storage at utility sites before YM opens.

In reality, the type of DPC or SPC used at each facility is highly individualized, depending on specific vendor contracts and site licenses. However, due to unavailable data, and to facilitate viewing results in units that are comparable, assumption of a generic container is necessary. TADs or DPCs loaded before the repository opens are assumed to remain in dry storage at the utility sites until the end of the shipping campaign unless there are not enough cool assemblies remaining in the pool to fulfill a scheduled shipment. This is assumed because it is expected that the utilities will generally desire to remove waste from their spent nuclear fuel pools prior to removing dry storage containers.<sup>4</sup> Future enhancements of the modeling tool will incorporate the flexibility to send dry storage containers prior to removing waste from the pool.

This analysis investigates the effect of varying the year the TAD is in use from 2012 to 2020 and the year the repository opens from 2020 to 2030. The final design specifications for the TAD were released in 2007, and it is expected to take at least five (5) years for the TAD to be licensed for commercial use. The earliest estimate for commercial availability for the TAD is 2012 (Kouts 2006b). An upper bound of 2020 for the availability is considered because that is the earliest date assumed for the repository opening in this analysis. DOE plans to submit a License Application (LA) to the U.S. Nuclear Regulatory Commission (NRC) in 2008 for construction authorization. Construction on Yucca Mountain can begin once the authorization is granted, and the earliest estimate for opening the repository is 2017 (Williams 2006). An earliest date of 2020 is applied instead of 2017 since delays may occur in the licensing and development

---

<sup>4</sup> Personal communication with Adam Levin, Spent Fuel and Decommissioning, Exelon Generation Company. December, 2006.

stages and the simulation begins with a full steady-state receipt rate, after the construction of the processing facilities is complete.

The draft SEIS for YM describes the repository as accommodating 63,000 MTHM of CSNF (or approximately 7,500 TADs), and for shipping to be completed in about 25 years, which equates to about 300 TADs per year (DOE 2006b). Therefore, each year after the repository is open, 300 TADs of allocations, dictating the amount that each facility loads, are assigned. As shown in Table 2, the shipping campaign planned for Yucca Mountain will not reach the full rate until the fifth year. This simulation commences at the full rate, and is limited to only CSNF shipments, for simplification purposes.

Most of the early shipments are expected to be non-commercial, which are estimated to have a lower thermal output than commercial shipments. Because these shipments will have a lower thermal output, and the ramp-up time is short relative to the complete lifetime of operations, the limitation of this simulation to CNSF shipped at a steady-state rate is not expected to greatly impact the resulting demand for aging above ground at YM. TADs will continue to be loaded according to the allocation schedule until the end of the shipping campaign, which is set to one of two durations. In one case, shipments are stopped after 7,500 TADs (approximately 63,000 MTHM) have been loaded. In the second case, the entire projected inventory of waste created from the reactor fleet is sent, roughly doubling the current capacity of Yucca Mountain.

Table 2

Spent Fuel Annual Capacity and Acceptance Priority Ranking Summary

| Year of Operation <sup>a</sup> | Quantity of SNF Shipped (MTHM) | Number of Purchasers With Allocations <sup>b</sup> | Range of Allocation Quantities (MTHM) <sup>c</sup> |
|--------------------------------|--------------------------------|--|--|
| 1                              | 400                            | 16   | 0.1 – 145  |
| 2                              | 600                            | 23   | 0.1 – 72   |
| 3                              | 1200                           | 26   | 0.1 – 251  |
| 4                              | 2000                           | 37   | 0.1 – 467  |

| 6                              | 3000                           | 39   | 0.1 – 452  |
| 7                              | 3000                           | 43   | 0.1 – 420  |
| 8                              | 3000                           | 47   | 0.1 – 375  |
| 9                              | 3000                           | 50   | 0.1 – 524  |
| 10                             | 3000                           | 46   | 0.1 – 444  |

<sup>a</sup> Years after Yucca Mountain is opened.

<sup>b</sup> The number of Purchasers with allocations for shipping commercial spent fuel. In some cases, Purchasers may have multiple allocations in a given year that are consolidated into one amount.

<sup>c</sup> The minimum and maximum allocated quantities of spent fuel to a single Purchaser that year (NAS 2006a).

The assignment of allocations is modeled by applying an incoming signal of 300 TADs each year to the GoldSim Allocator Element, which then splits the signal among the waste generation sites, applying pre-defined demands and priorities. In this way, a discrete event triggers each shipping transaction. Fig. 2 shows the high level logic for how Purchasers assign or trade allocations to each of their pools. If Purchasers are allowed to trade allocations, all pools are considered in the same Allocator Element which distributes 300 allocations per year. If Purchasers are not allowed to trade allocations, a separate Allocator Element is used for each Purchaser that is only linked to that Purchaser's pools. The incoming allocations for these separate Allocator Elements are based on the *Allocation Priority Ranking and Annual Capacity Report (APR/ACR)*, with a few adjustments to facilitate the TAD concept (DOE 2004).

The APR/ACR assigns allocations in MTHM to Purchasers based on the order that fuel was discharged (DOE 2004). Mergers and acquisitions have taken place since the APR/ACR was established in 2004, and it is not clear if Purchasers will adjust their contracts accordingly. In an attempt to account for allocation sharing that might be facilitated by owner/operator consolidations since 2004, the "Purchasers" have been altered to reflect current corporate ownership.

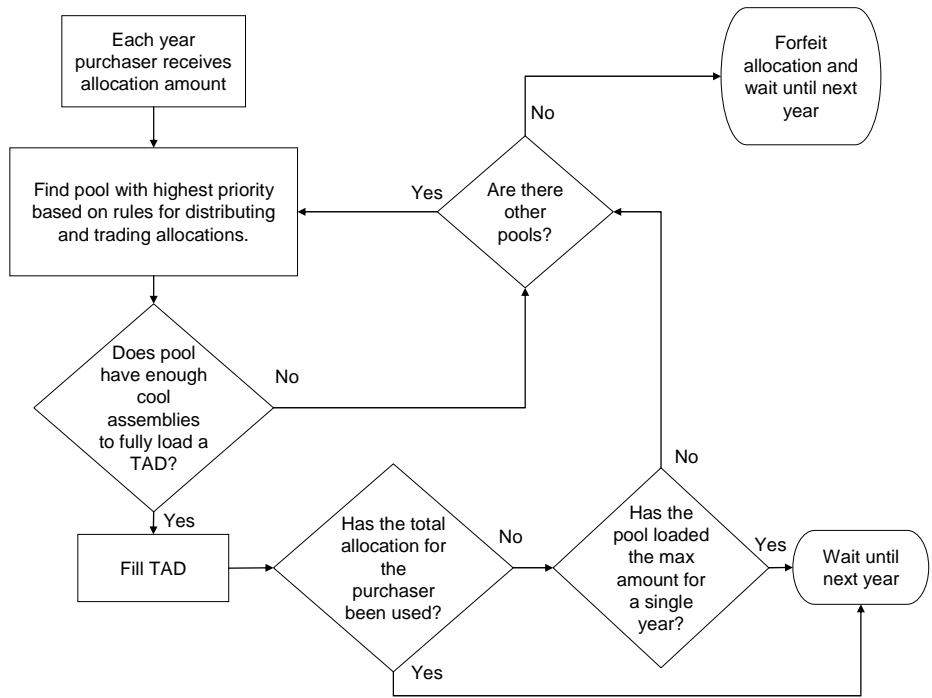

Fig. 2. Process flow for distribution of allocations for shipments.

Table 2 describes the number of Purchasers with allocations, and the range of individual allocation quantities, for the first ten years of the shipping campaign for YM. As shown, many of the allocations are smaller than the amount needed to fully load a TAD. Because it is uneconomical to ship TADs that are not fully loaded, the allocations are assigned in units of TADs (as opposed to MTHM). Allocations are still assigned based on order that fuel was discharged from the reactor, only the order is based on the date that each equivalent of a full TAD had been discharged, as opposed to individual assembly weight, rounded to a tenth of a metric ton.

The APR/ACR implies that Purchasers will distribute allocations to their pools (DOE 2004). However, the report does not specify *how* allocations must be prioritized. Purchasers may distribute their allocations according to the age of the fuel in their inventory. However, they might choose to distribute allocations giving priority to the facility with the least remaining capacity in its pool in order to avoid dry storage costs. This will depend on the economic circumstances of the transaction.<sup>5</sup> A further variation of the APR/ACR method is to allow utilities to *exchange* allocations with other Purchasers in possession of even younger fuel, or with less remaining capacity in their pools.

Table 3 summarizes the parameters varied in this analysis and the values explored for each parameter, as well as the 81 scenarios that were considered. Eight sub-scenarios were created by manipulating four variables (year TAD becomes available, year YM opens, transportation thermal limit, and emplacement thermal limit) from their high to

---

<sup>5</sup> Personal communication with Everett Redmond, Used Fuel Storage and Transportation, Nuclear Energy Institute, June 27, 2007.

low values while holding all others at their central value). A ninth sub-scenario was defined holding each variable at its central value. These *nine* sub-scenarios were considered in combination with *three* utility assembly selection loading behaviors, creating 27 combinations of sub-scenarios with assembly selection orders. This set of 27 scenarios was repeated 3 times: assuming that Purchasers did not trade allocations with a capacity of 7,500 TADs for YM, assuming Purchasers could trade allocations based on age with an expanded capacity of YM, and assuming that Purchasers could trade allocations based on least remaining capacity in the spent nuclear fuel pools with a capacity of 7,500 TADs.

As shown in Table 3, the loading of spent fuel assemblies from a facility's pool into dry storage containers follows one of three algorithms: (1) oldest fuel first (OFF), (2) youngest fuel first at least five years old (YFF5), or (3) youngest fuel first at least ten years old (YFF10). The YFF5 and YFF10 algorithms load the youngest assembly that still meets the per-assembly heat limit, meaning that if the per-assembly limit is very low, then fuel that is five or ten years old may be too hot to qualify for shipping.

The PWR and BWR TADs are expected to accommodate zone loading, meaning that TAD canisters are loaded with relatively hotter assemblies in the center and cooler assemblies around the outer perimeter to improve shielding and reduce risk of worker dose. It is recognized that an opposite configuration with hotter fuel on the outside as opposed to the center is also applied in some cases in order to improve thermal heat transfer properties of the canister.<sup>6</sup> The particular configuration is not as important as the fact that hotter and cooler assemblies with different relative decay curves will be co-

---

<sup>6</sup> Personal communication with Kris Cummings, Manager DOE Programs, Holtec. July 25, 2007.

mingled in the same TAD canister. The 21-PWR and 44-BWR TADs will most likely be designed to hold 9/12, or 20/24 hot/cold assemblies, respectively. The per-assembly thermal power output limit for the hotter zone is designed to be twice that of the cooler zone. For example, the per-assembly limit for a 25 kW, 21-PWR TAD is 1.67 kW for each of the 9 hotter assemblies and 0.83 kW for each of the 12 colder assemblies.<sup>6</sup> The transportation limit for the TAD is assumed to range from 18 kW to 25 kW since these are the ranges considered in the performance specifications released by DOE (DOE 2007).

|                  |                                | YFF5               | R1-R9                 |
| 14,000 TADs      | Based on age of SNF            | OFF                | R1-R9                 |
|                  |                                | YFF10              | R1-R9                 |
|                  |                                | YFF5               | R1-R9                 |

Each facility is permitted to send a maximum of ten TADs per year, which is considered a reasonable upper limit to load at a specific facility in a given year<sup>7</sup>, without placing undue stress on resources. Currently, facilities load about six to eight dry storage containers approximately every two years to accommodate core off-load, but loading campaigns are likely to increase once shipments to Yucca Mountain commence. This limit also corresponds to the number of TADs that could be accommodated by two dedicated trains, assuming each carries five TADs. The Supplemental Environmental Impact Statement (SEIS) analyzes the impacts of sending as many as five transportation casks on a single dedicated train (DOE 2002).

Fig. 3 illustrates the flow of packages upon arrival at YM that is assumed in this study. In this particular analysis, flow through the surface facilities is constrained *only* by the thermal limitation on emplacement. Each year, the surface facilities are assumed to process and emplace all packages arriving, or in the Aging Facility, that meet the thermal criteria. In reality, processing capacities will also be a constraining factor, but it is important to *isolate* delays due to thermal constraints from delays due to capacity constraints.

---

<sup>7</sup> Personal communication with Steve Edwards, Spent Fuel Management Progress Energy. June 20, 2007.

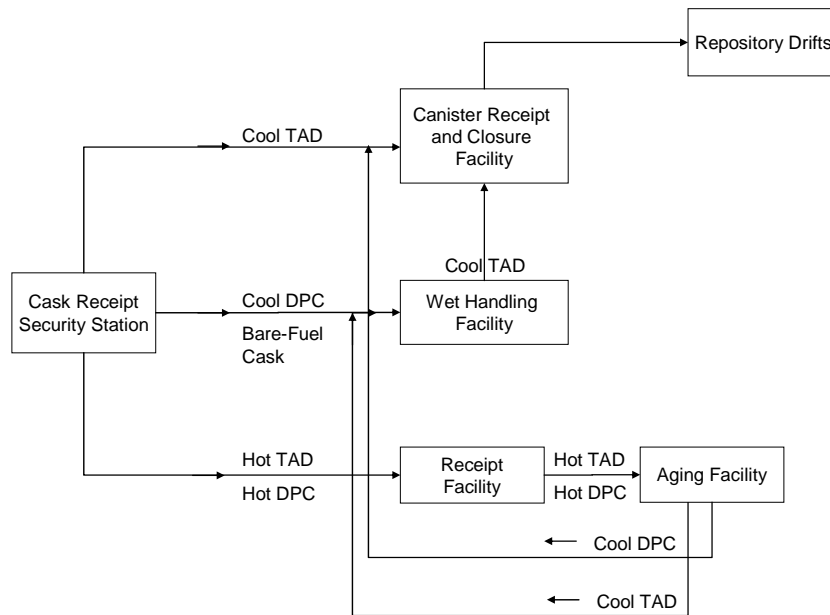

Fig. 3. Yucca Mountain repository surface facilities process flow logic assumed in this analysis.

As discussed previously, the thermal emplacement limit currently documented is 11.8 kW per TAD. Scenarios in which the emplacement limit is defined as 18 kW are analyzed in this study to understand the potential impact on above-ground aging requirements at YM of changing the emplacement limit. Although it has not yet been shown if this emplacement limit will allow the repository to stay within the thermal management criteria, the NWTRB is encouraging DOE to explore the potential for easing this constraint (NWTRB 2006).

Upon arrival at the repository, TADs that are below the emplacement heat limit are routed to the Canister Receipt and Closure Facility (CRCF) before being emplaced. Canisters above the emplacement limit are sent to the Aging Facility, via the Receipt Facility (RF), where the TAD or DPC is placed in an aging overpack. When DPCs meet the thermal emplacement limit, they are taken to the WHF. When TADs meet the thermal emplacement requirement, they are removed from the Aging Facility and sent to the CRCF before being emplaced.

Process flow in this study is slightly simplified from that described in the SEIS. In the SEIS, the design calls for most of the hot canisters to be processed in the RF, but the CRCF will also have the capability, if necessary, to place canisters in aging overpacks to be sent to the Aging Facility. The process flow described in Fig. 3 is different from the SEIS because it does not route TADs from the CRCF or the WHF to the AF, or from the RF to the CRCF. It also does not route DPCs to the CRCF (DOE 2006b).

Yucca Mountain design documents stipulate that there may be up to three CRCFs constructed, each capable of processing 450 MTHM/year of TADs for direct emplacement and 200 MTHM/year of TADs for transfer to the Aging Facility (BSAIC

2007c). The RF will be designed to process up to 1,000 MTHM/year of TADs and 150 MTHM/year of DPCs (BSAIC 2007d). The Aging Facility will accommodate 2,500 TADs and is expected to be necessary for 50 years, after which all the waste will have been emplaced (DOE 2006b).

It is important to emphasize that the model does not simulate emplacement sequencing or ventilation within the repository drifts. The model calculates the thermal power output of each individual CSNF package, but does not attempt to estimate line loads within the emplacement drift. The modeling of subsurface repository behavior is considered outside the scope of this study. Instead, the focus of this analysis is on the storage requirements of the waste generators, the efficiency of allocation of transportation shipments, and the above-ground aging needs at YM.

### ***Overview of Major Assumptions***

This section highlights major assumptions made in the development of system constraints. The rationale for these assumptions was addressed in the previous section along with the system constraints.

Major assumptions include:

- Facilities load dry storage only when demand for their pools exceeds licensed capacity.
- Facilities simultaneously and unanimously adopt the use of the TAD when it is commercially available.

- TADs accommodate zone loading of 9/12 and 20/24 configurations with the hotter assemblies having approximately twice the thermal limit than the outer assemblies.
- TADs and DPCs loaded before the repository opens remain on the dry storage pads until there are not enough cool assemblies in the pool to fulfill the allocation.
- TADs and DPCs loaded before the repository opens will eventually be sent to YM to be repacked in the WHF.
- Purchasers are updated to reflect current ownership of facilities.
- Allocations are assigned to Purchasers in units of TADs instead of MTHM.
- The amount of 10 TADs per year is a reasonable maximum limit for a single pool to load and send to YM in a given year.
- Surface facilities process and emplace all packages above the thermal emplacement limit each year.

### *System Performance*

The model estimates operational performance of the waste management system by measuring response variables associated with characteristics of the system.

Dependent response variables are measured as cumulative counts each year of:

- Assemblies in wet storage at utility sites
- Dry storage canisters loaded and placed in storage at utility sites
- Pools loading dry storage for shipments to YM

- TADS and DPCs shipped to YM
- TADs or DPCs at YM that are above the emplacement limit
- TADs at YM that are below the emplacement limit

Scenarios are examined to determine which, if any, result in adverse effects (e.g., delays in waste acceptance beyond the receipt rate, aging requirements above the planned capacity for the Aging Facility, etc.), and which improve operational performance (e.g., more efficient use of transportation movements and reduced storage requirements relative to other scenarios). Variables are evaluated in terms of their relative importance to the performance of the system (e.g., which variables have the most influence over the expected dry storage demands or aging requirements).

## **Discussion of Results**

### ***Utility Storage Demands***

Storage demands at the utility sites can be described as: (1) DPCs destined for Yucca Mountain, (2) TADs destined for YM, and (3) storage for waste in addition to what will eventually be sent to YM. The current 70,000 MTHM capacity will not accommodate the projected volume of spent fuel assemblies in excess of pool storage capabilities. Unless more than 70,000 MTHM is permitted to be sent to YM, or a second repository is opened, facilities may need to load dry storage containers that will not be sent off-site. Since the utilities may view the burden of these storage categories differently in terms of economic, legal or health and safety implications, treating them separately has merit.

### Storage of DPCs Loaded Before YM Opens

As of 2002, about 4,200 MTHM of CSNF had been loaded into dry storage. Assuming nine MTHM per TAD-sized container, this amount is approximately equivalent to 460 TAD-sized containers.<sup>8</sup> Fig. 4 shows that as many as 2,000 containers of this size will need to be loaded before a potential opening of YM in 2020. This number increases to 3,750 containers if YM is delayed until 2030. Depending on when the TAD is in use, more or less of these containers will be DPCs as opposed to TAD canisters. Referring to Fig. 4, one can measure the percentage of containers destined for YM that are expected to be in non-TAD form, assuming that all facilities use the TAD as soon as it is available. The percentage ranges from 12% to 28% assuming that TADs are in use by 2012 or 2020, respectively.

The YM pre-closure safety analysis assumes that a significant majority (~90%) of the waste sent to YM will be in TADs, so a delay in the TAD will have implications on the surface facility operations unless utilities repackage waste into TADs (DOE 2006e). The safety benefits of using the TAD will largely rely on the percentage of waste loaded into DPCs or SPCs at the time that YM opens. In order to fully realize the safety benefits of the TAD design, the number of DPCs/SPCs that need to be repackaged should be limited to close to 10% of the total waste stream sent to YM. Since the percentage of TADs that may need to be loaded with waste that was previously in DPCs/SPCs more than doubles from 2012 to 2020, it is important to commercialize the TAD by 2012.

---

<sup>8</sup> Assuming 425kg per PWR assembly, a 21-PWR container is 8.9 MTHM. Assuming 175kg per BWR container, a 44-BWR container is 7.7 MTHM. The amount of 460 DPCs or single-purpose containers is an estimate of the *equivalent number of TADs* that were in dry storage as of 2002, and does not represent the precise number of DPCs or single-purpose containers actually loaded since there are several different sized containers in use.

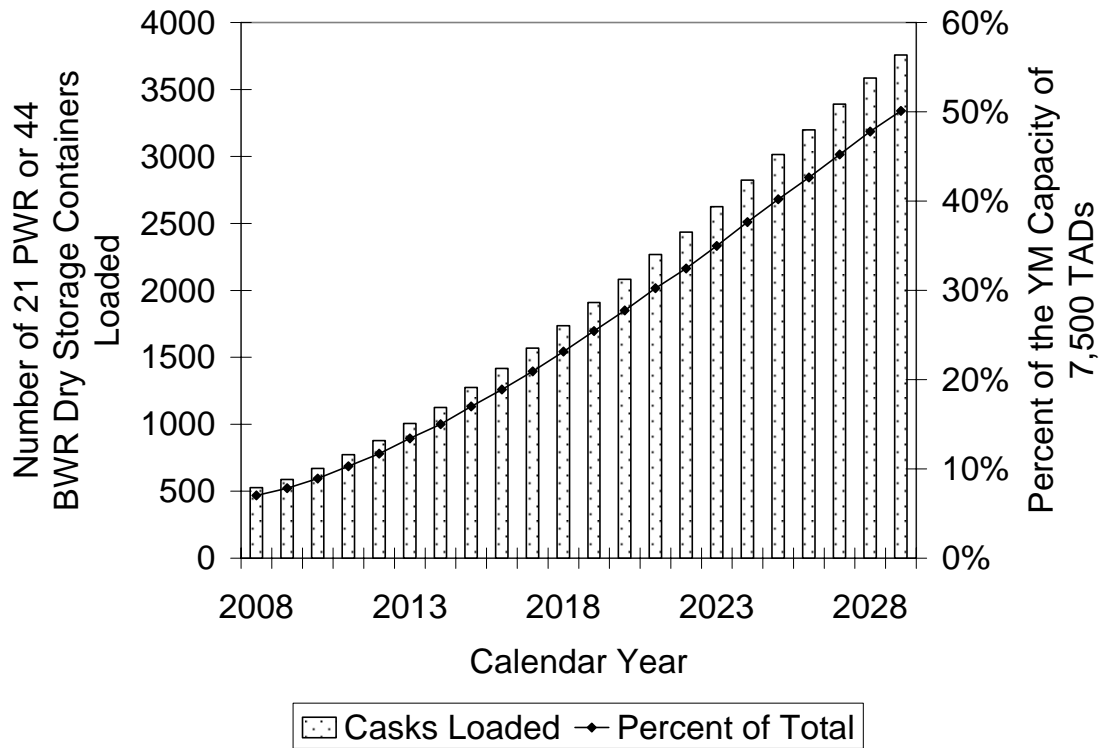

Fig. 4. Cumulative number of dry storage containers loaded before 2030 due to lack of capacity in the SNF pools (also shown as percentage of total capacity, or 7,500 TADs, to be replaced in YM).

### Storage of TADs

Before the repository opens, the number of TADs that utilities will need to store is entirely dependent on the year the TAD is in use and the year the repository opens. As shown in Fig. 4, this number could vary considerably. Also, in cases where a facility needs to load dry storage *after* YM is open, but the facility does not have a shipment scheduled, the TAD(s) will be placed on the dry storage pad at the utility site instead of being shipped directly to YM.

It is expected that utilities may prefer to free up capacity in the pool over removing containers from the dry storage pad.<sup>9</sup> Therefore, TADs placed on storage pads at the utility sites are assumed to remain there until the end of the shipping campaign or until a facility does not have enough cool assemblies in its pool to fulfill an allocation. Because the majority of TADs that need to be stored at the utilities are loaded *before* the repository opens, the maximum number of TADs stored on the utility sites' pads is not impacted by the assembly selection assumptions, but rather by the year the TAD is in use and the year YM starts accepting waste. Fig. 4 shows that as many as 1,900 out of the 3,750 containers loaded before 2030 could be TADs if it is in use by 2012. This is approximately one quarter of the 7,500 TADs that will eventually be emplaced.

### Additional Storage Requirements

An additional category of demand at the utility sites is that needed for waste beyond what will be sent to YM under the current legal capacity limit. This performance metric

---

<sup>9</sup> Personal communication with Everett Redmond, Used Fuel Storage and Transportation, Nuclear Energy Institute, June 27, 2007.

is sensitive to the year that YM starts receiving waste and the allocation trading rules that are enforced.

Fig. 5 shows the impact of trading allocations on this category of storage. The scenario categories are listed along the x-axis. “Trading within Subscenario” represents whether or not trading was assumed (Yes or No), and the subscenario conditions R1 – R9 (Table 4). As expected, allowing Purchasers to trade allocations based on least remaining capacity in the reactor site spent nuclear fuel pool decreases the overall expected dry storage remaining at the sites when YM reaches capacity. The tradeoff is that more fuel will remain in the reactor site pools. A paired t-test with an alpha level of 0.05 (Appendix B) shows that the difference in dry storage demands at the utility sites between scenarios that allow trading based on least remaining capacity and those that do not is significant. This is true irrespective of the subscenario R1-R9 assumptions.

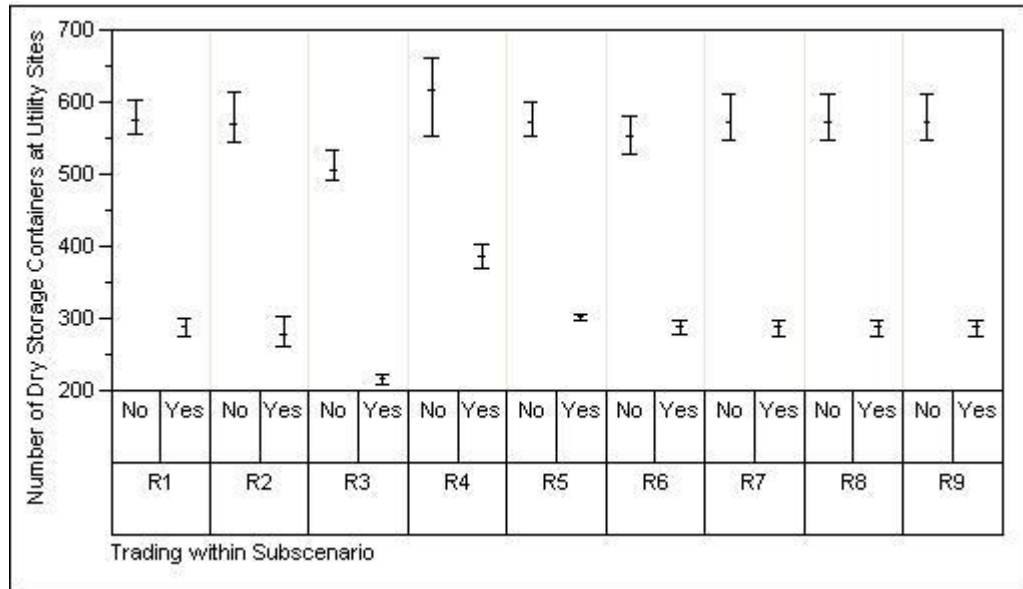

Fig. 5. Effect of trading allocations (yes or no) on expected aggregate demand for storage at the waste generation sites in the year that YM reaches current legal capacity in terms of number of 21-PWR or 44-BWR sized containers for each subscenario (R1-R9), showing the range of values and the means.

## ***Transportation***

In terms of transportation, it is desirable to avoid delays in the shipping campaign, but also to maximize the use of each transportation movement (using dedicated trains) for efficiency. These two goals are potentially competing if dedicated trains are held at a specific site until the maximum number of packages that can be sent on a single train have been allocated and loaded. Therefore, it is anticipated that scenarios which increase the efficiency of dedicated trains without delaying the shipping campaign will be preferred. A prior analysis concluded that variations in transportation limits and loading rules did not significantly impede the rate of shipments under the current YM capacity but that lowering the transportation limit could disrupt shipment schedules if the capacity of YM was greatly increased (Spradley, Abkowitz and Clarke 2008; Appendix D).

This study shows that variations in the waste acceptance rules can improve the efficiency of using dedicated trains for shipments. Scenarios in which Purchasers are permitted to trade allocations result in more efficient use of dedicated trains because the same amount of waste is shipped to YM each year, but from a fewer number of facilities (Fig. 6). Prohibiting trade between Purchasers prevents the most efficient use of trains because, in most cases, the total allocation is not evenly divisible by the maximum limit for each train. Trading allocations decreases the number of facilities making shipments because allocations are consolidated so that facilities send ten TADs per year more frequently. A paired t-test (Appendix B) shows that the difference in number of pools making shipments is significant with an alpha level of 0.05. This is true irrespective of the subscenario R1-R9 assumptions.

Fig. 6. Effect of trading allocations (yes or no) on the number of pools sending shipments in a given year for each subscenario (R1-R9), showing the range of values and the means.

### ***Aging Above Ground at Yucca Mountain***

Demand for aging above ground at YM is measured by the amount of waste aging above ground over time and the length of time the Aging Facility is required. A prior analysis established that the thermal limits for transportation and emplacement are important variables with respect to peak required capacity of the Aging Facility at YM, especially if younger fuel is sent first (Spradley, Abkowitz and Clarke 2008; Appendix D). This analysis provides the opportunity to describe the influence of the waste acceptance assumptions and emplacement limit on above ground aging requirements in greater detail.

Sending oldest fuel, and allowing 18 kW packages to be emplaced, requires the least amount of aging. The most aging is required when the youngest fuel is sent first and the emplacement limit is kept at 11.8 kW. Purchasers are not likely to distribute allocations so that the youngest fuel (at least five years old) from *all* of their facilities is sent each year, because there is no known incentive to do so. However, there is nothing in the *Standard Contract* preventing this from occurring, so it is important to consider the implications of such a scenario (10 CFR § 961 (2008)).

In the case that youngest fuel is sent first to YM starting in 2025, and the emplacement limit is kept at 11.8 kW (shown as the maximum range in Fig. 7 (c)), the number of TADs aging in a given year could reach over 3,500. This is an approximate 40% increase over the planned 2,500 spaces currently in the Aging Facility design, and almost one-half of the assumed 70,000 MTHM to eventually be emplaced. Still, if the emplacement limit is increased to 14.9 kW (Fig. 7 (b)) or 18 kW (Fig. 7 (a)), the required aging is drastically reduced, even if youngest fuel is sent first.

Fig. 7. Impact of thermal emplacement limit on the above-ground aging requirements at YM. Cell means and ranges of the OFF, YFF10, and YFF5 scenarios are shown for each year.

- (a) 18 kW emplacement limit (R7)
- (b) 14.9 kW emplacement limit (R9)
- (c) 11.8 kW emplacement limit (R8)

Demand on the Aging Facility is also illustrated in Fig. 8 (a) and (b). These charts compare the number of containers aging and the length of time the Aging Facility is occupied under various scenarios for utility selection of assemblies for loading and rules for trading allocations. Allowing Purchasers to trade does not greatly increase the number of canisters in the Aging Facility in the scenarios *when younger fuel is sent first*. While a paired t-test with an alpha of 0.05 (Appendix B) shows that the difference in the *average duration* of the aging facility is significant, the difference in the *maximum duration* (indicated by the top of the range bar) is small under most subscenarios. The paired t-test also shows that the difference between the number of canisters aging is significantly greater for the scenarios that allow trading in the case that oldest fuel is sent first. However, for the younger fuel scenarios, the difference between the trading and non-trading scenarios is not significant.

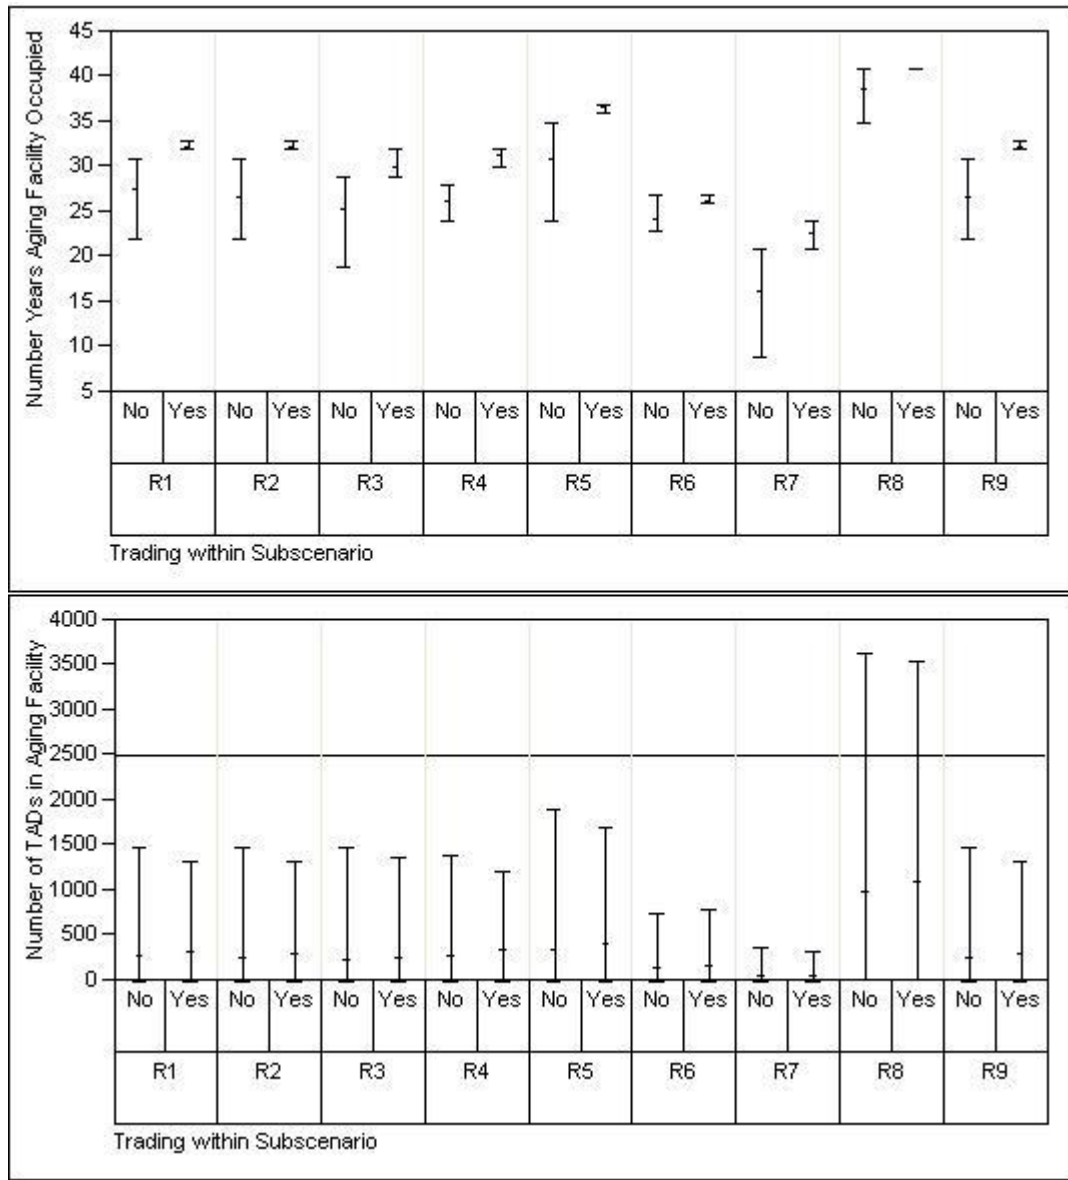

Fig. 8. Effect of trading allocations (yes or no) on demand for the Aging Facility at YM for each subscenario (R1-R9), showing the range of values and the means.

## Conclusions and Recommendations

This chapter describes the development and application of a model to explore the impact of waste management system design and operations on storage demands at the utility sites, efficiency of transportation movements, and aging requirements at YM. The model provides an opportunity to perform analyses of various Yucca Mountain pre-closure operating scenarios with the goal of understanding system interactions, offering the potential to recognize trade-offs and dependencies.

Response indicators are associated with characteristics of waste acceptance, transportation, and surface facility operations. Overall, scenarios are evaluated for their potential to result in desirable characteristics in all three areas of the waste management system. The results indicate that allowing Purchasers to trade allocations, prioritizing the trades based on least remaining capacity in the reactor site spent nuclear fuel pools, reduces the dry storage demands at the utility sites and the average number of pools making shipments in a given year, while increasing the efficiency of the dedicated trains. While this type of prioritization for allocations does impact the amount of aging if oldest fuel is sent first, it does not under the YFF5 and YFF10 scenarios.

In the next chapters a discussion is provided of the use of the tool to explore the impact on *safety* of various waste streams as well as address the ability of the surface facilities to process likely demand. Canisters that need to be aged due to thermal or capacity constraints will require more crane transfers than those that are not aged. The safety implications will depend on the crane reliability assumed as well as the number of handlings required under the various scenarios.

## CHAPTER III

### SAFETY CONSIDERATIONS

#### Abstract

This chapter focuses on the safety implications of an assumed waste stream. The analysis employs a model developed over the course of this research for predicting the packaging and thermal characteristics of the waste stream arriving at Yucca Mountain. The model generates waste streams for commercial spent nuclear fuel (CSNF) as a function of repository design parameters and operating strategies, accounting for the expected number of material crane transfers.

This application of the model explores changes in assumptions regarding the following parameters: (1) year the TAD becomes available, (2) year that YM opens, (3) thermal limit for emplacement, (4) thermal limit for transportation, (5) utility approach to selection of assemblies from the SNF pool for dry storage loading, and (6) utility approach to selection of dry storage containers for shipment to YM.

The response variables measured are the counts of: (1) dry storage containers loaded due to lack of capacity in the spent nuclear fuel pools before YM starts to receive waste, (2) TADs that could potentially be loaded assuming that utilities begin using the TAD as soon as it is commercially available, (3) packages arriving above or below the emplacement limit each year, (4) packages in the Aging Facility at YM each year, (5) packages in the Aging Facility that are thermally cool enough to be removed from the Aging Facility each year, and (6) material transfers at the surface facilities.

Through application of a simplified routing scheme for waste processing at surface facilities, packages that are above or below the emplacement limit each year are used to determine material transfers. The likelihood of the number of occurrences during the 50-year pre-closure operational period of three internal events involving crane transfers are estimated: (1) drop of a bare-fuel assembly, (2) drop of a transport, aging, and disposal canister (TAD), and (3) drop of a Dual-Purpose canister (DPC). The analyses indicate that scenarios requiring more canisters to be aged at YM, as well as scenarios that include more DPCs, require a greater number of expected total package handlings, and hence result in a higher frequency of a drop.

Results indicate that DOE estimates are within the likely range of frequencies that is generated by this analysis. Also, the consequences of these events are low enough that their frequency will not likely impact the ability to meet regulatory requirements. Still, considering the inconclusiveness surrounding future waste schedule negotiations, DOE could strengthen its preliminary hazards analyses by adopting a probabilistic approach to estimating the frequencies of drop events in evaluating pre-closure safety. This would help to communicate the risk posed by the drop events, and allow for an analysis that is less reliant on deterministic estimates of waste stream quantities and crane drop rates.

## Introduction

### *Yucca Mountain Pre-Closure Waste Management System*

The Nuclear Waste Policy Act of 1982 as Amended, hereafter referred to as NWPA, tasked the U.S. Department of Energy (DOE) with the design, construction, and operation of a geologic repository for the nation's high-level nuclear waste (HLW) at Yucca Mountain (YM), NV (42 USC § 10101 (2008)). The site was deemed suitable by President George W. Bush in 2002, and DOE is in the process of preparing a license application (LA) for construction and operation of the repository. The LA will describe how the repository is expected to operate during the pre-closure and post-closure phases, and demonstrate that expected behavior complies with dose consequence regulations and standards.

Pre-closure operation consists of the components, facilities, and activities at the surface facilities that collectively work to prepare waste for disposal, and emplace it in the repository. Pre-closure also includes the packaging of waste *at the generation sites* and transportation from the generation sites to the YM surface facility, although the potential dose consequence resulting from these activities is outside the scope of the LA. Post-closure evaluations focus on the potential migration of radionuclides through the subsurface to the Reasonably Maximally Exposed Individual (RMEI) at the point of compliance once the repository is closed.

An important constraining parameter of pre-closure operations is *temperature* because the waste must be below a specified thermal energy (kW) before it can be emplaced. The repository design calls for most of the waste to be packaged at the utility

sites in a transport, aging, and disposal canister (TAD), which will be placed inside a transportation overpack and sent to YM. Waste that is not in TADs will arrive at the repository either in transportation casks carrying bare-fuel assemblies or Dual-Purpose canisters (DPC).

Upon arriving at YM, waste will be prepared for emplacement at the surface facilities. The surface facilities at the repository will be used for the following functions:

- The Initial Handling Facility (IHF) will receive DOE HLW and Naval SNF, and prepare it for emplacement.
- The Canister Receipt and Closure Facility (CRCF) will primarily transfer TADs from transportation overpacks to disposal overpacks for emplacement, but it will also be able to transfer TADs or DPCs to aging overpacks to be sent to the Aging Facility. The CRCF is also capable of transferring DOE HLW and SNF canisters to disposal packages. DOE plans to construct as many as three CRCFs in a phased approach.
- The Wet Handling Facility (WHF) will receive DPCs and bare-fuel transportation casks. Each DPC or transportation cask will be placed in a pool and the assemblies within it will be transferred to a TAD. The TAD will then be removed from the pool and sent to the CRCF or placed in an aging overpack and sent to the Aging Facility.
- The Receipt Facility (RF) will primarily function to receive TADs or DPCs containing fuel that is too hot to be emplaced, and transfer the canisters into aging overpacks to be sent to the Aging Facility. However, the RF can also be

used to handle canisters that are cool enough to be emplaced, but nevertheless require aging due to bottlenecks in the CRCF or WHF.

- The Aging Facility is a set of concrete pads where TADs or DPCs that need to be aged are placed.

DOE is in the process of carrying out a pre-closure safety analysis to systematically examine the potential hazards and dose consequences resulting from the activities taking place at the YM surface and subsurface facilities. In its review of the LA, the Nuclear Regulatory Commission will determine if DOE sufficiently demonstrates that it can construct and operate the repository in compliance with regulations and standards developed by NRC and the Environmental Protection Agency (EPA). As of January 2008, EPA had not finalized its public dose compliance standard, but the final decision is not expected to impact the review of *pre-closure* safety.

### ***Regulatory Framework of the YM Pre-Closure Waste Management System***

The following parts of the Code of Federal Regulations apply to the Yucca Mountain Project (DOE 2006e):

- 10 CFR § 63: Energy: Disposal of High-Level Radioactive Wastes in a Proposed Geologic Repository at Yucca Mountain, Nevada
- 10 CFR § 20: Energy: Standards for Protection Against Radiation
- 40 CFR § 197: Protection of Environment: Public Health and Environmental Radiation Protection Standards for Yucca Mountain, Nevada.

These regulations provide the public and worker dose standards and guidance for repository design objectives. The pre-closure safety analysis portion of the LA is

expected to draw on previous analyses documented in DOE's Preliminary Pre-Closure Hazards Analysis (PHA) (DOE 2006e). DOE characterizes "hazards analysis" as an approach used to determine the likelihood of potential radiological hazards (events) that could result in public or worker dose consequences during pre-closure operations. The author refers to this approach as a "risk analysis", but will subsequently use the term hazards analysis, or the abbreviation PHA, to be consistent with DOE's terminology. The PHA evaluates events that are initiated by *external* forces (e.g., earthquake, extreme wind, etc.) as well as generic *internal* events (e.g., drop, collision/crushing, fire, etc.). The main elements of DOE's hazards analysis are event identification, event frequency categorization, and event consequence analysis (e.g., what can happen, how likely it is, and what are the consequences) (Kaplin and Garrick 1981).

The frequency of occurrence for pre-closure events is defined as the likelihood of the event occurring during the entire 50 years of emplacement operations (DOE 2006e). If the expected frequency of occurrence is greater than one, the event is defined as a *Category 1* event sequence. Events that are not expected to occur one or more times, but have at least one chance in 10,000 are defined as *Category 2* event sequences. Any event with less of one chance in 10,000 is considered *Beyond Category 2* (DOE 2006e). The categories exist because the regulatory dose requirements are defined separately for events in each category (Table 5). Dose requirements are not defined for Beyond Category 2 Events.

Table 5

Total Effective Dose Equivalent (TEDE) Regulatory Limits

| Event Type                             | Worker  | On-site Public  | Off-site Public                    |
|--|---|---|------------------------------------|
| Normal Operations or Category 1 Events | 0.05 Sv (5 rem)/yr <sup>a</sup><br>5 mSv (500 mrem)/yr <sup>b</sup> | 1 mSv (100 mrem)/yr <sup>c</sup><br>0.02 mSv (2 mrem)/hr <sup>c</sup> | 0.15 mSv (15 mrem)/yr <sup>d</sup> |
| Category 2 Events                      | N/A <sup>e</sup>  | 0.05 Sv (5 rem)/event <sup>f</sup>                                    | 0.05 Sv (5 rem)/event <sup>f</sup> |

<sup>b</sup>10 CFR § 20.0011: “All worker and public exposures to ionizing radiation must be kept as low as reasonably achievable (ALARA).”

<sup>c</sup>10 CFR § 20.1301

<sup>d</sup>10 CFR § 63.204

<sup>e</sup> Potential worker dose consequences do not need to be estimated for Category 2 events.

<sup>f</sup>10 CFR § 63.111(b)(2)

## Research Objectives

For certain events involving material transfers (e.g., the drop of a CSNF assembly), the frequency over the pre-closure period can be estimated by applying a reliability rate of equipment to the number of times a specific action using the equipment occurs. Still, estimating the frequency is complicated by uncertainty regarding the *crane drop rate* and the *number of transfers* per item.

While data is available from the many crane lifts that have taken place in industry, the majority of recorded lifts are of fuel assemblies, which are lighter than canisters or transportation casks, and are uniform in shape and size for most facilities. The lifts that will take place at YM will be different in that they will consist of mostly heavy loads of different geometries. Meanwhile, the *number of transfers* will depend on the waste stream (e.g., the quantities of various casks, canisters, and SNF assemblies, as well as their thermal characteristics).

This research aims to gain a better understanding of the safety implications of a drop event through the following objectives:

- Review the crane drop rate and waste stream assumptions made by DOE in estimating the frequency of drop events during the 50-year pre-closure operational period.
- Discuss how the frequency categorization and dose consequence of the pre-closure events relate to the regulatory dose requirements.
- Generate multiple waste streams, as a function of repository design parameters and operating strategies, in order to estimate the range in the

number of material transfers that might be necessary at the surface facilities at YM.

- Use the data generated for the number of transfers to investigate the likelihood of the number of occurrences of a drop during the 50-year pre-closure emplacement period.
- Compare the results to DOE's estimated frequencies in the PHA.

## **Review of Pre-Closure Preliminary Hazards Analysis**

### ***Waste Stream Assumptions***

The quantities assumed by DOE to be processed in the surface facilities stem from a report titled the *2002 Operational Waste Stream and 2003 Total System Life Cycle Cost (TSLCC) Waste Stream Backup Calculation* (DOE 2003). This report documents the use of a model<sup>10</sup> developed by DOE to predict two potential waste streams for YM: (1) 2002 Operational Waste Stream (OWS), and (2) 2003 TSLCC Waste Stream. The study assumes 'allocations'<sup>11</sup> for waste shipments are assigned directly to the facility at which the waste was generated, giving priority to those in possession of the oldest fuel. However, since waste generators are not obligated to select the oldest fuel for shipment, a variety of selection criteria are explored. One such case, referred to as "Case B" in the

---

<sup>10</sup> CALVIN Version 3.1

<sup>11</sup> Allocation is defined as an amount that a waste generator may ship to YM in a given year.

study, assumes that waste generators select their youngest fuel first, as long as it has been out of the reactor for at least 10 years.

DOE derives the 2002 Operational Waste Stream from the existing inventory in the 1998 RW-859 Data Set, including the number of DPCs that had been loaded as of then, as well as projected inventories that assume a certain number of license extensions are granted (DOE 2003). The approach used by DOE to generate these particular waste streams allows for “short-loading” transportation casks (not loading them to full capacity) in order to comply with thermal limits for transportation when loading hotter fuel.

The approach assumes the allocations are used for the specific reactors earning the allocation, and therefore does not account for allocation sharing among facilities owned by the same Purchaser<sup>12</sup>, or allocation trading between Purchasers. The reader is referred to the *Standard Contract* and the *Allocation Priority Ranking and Annual Capacity Report* for a detailed description of the basis for assigning allocations (10 CFR § 961; (DOE 2004). A short description of the basis for this assumption is in the following excerpt from the *2002 Operational Waste Stream and 2003 Total System Life Cycle Cost (TSLCC) Waste Stream Backup Calculation* (DOE 2003):

“CSNF acceptance deliveries are assumed to be from the reactor generating each allocation, with no provisions for allocation trading. Under the *Standard Contract*, each Purchaser has the right to waste selection, and may select CSNF assemblies from any of its reactors up to the total of the MTHM delivery allocation earned by one of its reactors. Different Purchasers also have the right to exchange allocation among themselves for which an approved delivery

---

<sup>12</sup> Purchaser is the term used to refer to an entity that has a contract with DOE for waste removal and may own one or more facilities where waste is generated.

commitment has been issued, subject to DOE approval. However due to the large uncertainty associated with the extent to which allocation trading may occur, it is assumed in this calculation that the reactor earning the delivery allocation also uses that delivery allocation.”<sup>13</sup>

The main difference between the OWS and the 2003 TSLCC Waste Stream is that the OWS assumes that 84 license extensions are granted, while the 2003 TSLCC assumes that only 16 are granted. Case B of these waste streams assumes younger fuel is removed from the pool at a particular site before dry storage is sent, causing the waste stream derived from an inventory with less total fuel (2003 TSLCC) to include more of the older fuel in dry storage (including DPCs) as part of the 70,000 metric tons of heavy metal (MTHM) legal capacity for Yucca Mountain. Approximately 63,000 MTHM of the 70,000 MTHM is to be commercial spent nuclear fuel (DOE 2002). As shown in Table 6, the 2003 TSLCC Waste Stream predicts that more waste is sent in DPCs than the OWS since the 2003 TSLCC includes a larger portion of the older fuel.

Although the report comparing the waste streams originally recommended Case C (strict youngest fuel first) as a bounding scenario, Case B was carried forward because it was considered a more realistic estimate (DOE 2003). It is not clear why variations of the OWS were not *also* carried forward, since doing so would not seemingly require an excessive burden on future analyses, and could have provided a better understanding of the sensitivity of results to the waste stream. Nevertheless, subsequent DOE analyses in the PHA rely on Case B of the OWS.

---

<sup>13</sup> Section 3.0, Assumption 5.0 of DOE. (2003). "2002 Operational Waste Stream and 2003 TSLCC Waste Stream Backup Calculation."ACC:CAL-CRW-SE-000002, Department of Energy Office of Civilian and Radioactive Waste Management, Las Vegas, NV.

The following discussion takes the reader through the assumptions that allow DOE to use the quantities presented in Table 6 to estimate the expected frequency of certain events in the PHA. The entire commercial inventory in the OWS is about 430,700 CSNF assemblies (187,400 PWR and 243,300 BWR). A portion of the full waste stream (103,070 PWR and 102,916 BWR assemblies) is assumed to be included in the 70,000 MTHM legal capacity of YM. Assemblies are categorized as arriving in DPCs, bare-fuel transportation casks, or TADS. Of the 469 DPCs in the waste stream, 55% are assumed to be PWR and 45% BWR. This ratio is based on facilities selecting their youngest assemblies, at least 10 years old, to fulfill allocations. DOE assumes each DPC holds 36 PWR canisters or 74 BWR canisters in order to estimate the number of assemblies arriving in DPCs (BSAIC 2007b).

By subtracting the number of assemblies arriving in DPCs, DOE calculates the number of assemblies that will arrive either in bare-fuel transportation casks or in TADs. Approximately 88% of the assemblies that are not arriving in DPCs are assumed to arrive in TADs, and the remaining 12% are assumed to arrive in bare-fuel transportation casks (BSAIC 2007b). The basis for this proportion of TADs to bare-fuel casks is not given, but the author supposes it to be related to the criteria that no more than 10% of the entire waste stream will be in non-TAD form (BSAIC 2007a). It may also stem from the fact that a few waste generator sites, that do not have the heavy-load crane capacity or rail access necessary to accommodate TADs, will use smaller bare-fuel truck transportation casks.

Table 6

DOE Alternative Waste Stream Comparisons

|                               | Assemblies in<br>Total Inventory | Dual Purpose<br>Canisters (DPCs) |
|-------------------------------|----------------------------------|----------------------------------|
| 2002 Operational Waste Stream | 430,700                          | 469                              |
| 2003 TSLCC Waste Stream       | 335,700                          | 1,637                            |

See Table 9 of Ref.(DOE 2003), Table 12 of Ref.(DOE 2003). The author has chosen to use the same number of significant figures as provided by DOE.

Table 7

Expected Waste Stream Quantities

|  | Item                                       | Expected Quantity |
|--|--|-------------------|
|  | CSNF assemblies shipped in bare-fuel casks | 21,730            |
|  | DPCs                                       | 469               |
|  | Utility TADs (loaded at utilities)         | 5,676             |
|  | Site-specific TADs (loaded in the WHF)     | 1,571             |

See Table 3-1 of Ref.(DOE 2006e), Table 9 Ref. (DOE 2003). The author has chosen to use the same number of significant figures as provided by DOE.

The assemblies arriving in DPCs or in bare-fuel transportation casks are blended into TADs in the WHF. These TADs are referred to as “Site-specific” TADs. Conversely, TADs that were loaded at the utility sites are referred to as Utility TADs. A summary of the quantities of various casks assumed by DOE to be processed in the surface facilities is given in Table VII. DOE uses these waste stream quantities in its PHA to predict the frequency of certain events.

The following sections review how DOE determines the expected frequency of the following three internal events: (1) drop of a TAD canister with breach in air, (2) drop of a DPC with breach in air, (3) drop of a fuel assembly under water. The predicted dose consequences of the events are also discussed to provide a context for potential risk implications on variations in the frequency of these events.

### ***Frequency of Events***

DOE estimates the frequency of an event resulting from a crane failure as

$$x = t * p * c \tag{Eq.(1)}$$

where  $x$  is the number of occurrences of a drop over the 50-year emplacement operational period,  $t$  is the number of transfers over the emplacement period (number of items multiplied by the number of transfers per item),  $p$  is the probability of a drop per transfer, and  $c$  is a conservative factor of 1.1.

## Crane Drop Rate Assumptions

DOE assumes a crane drop rate involved with handling canisters and spent nuclear fuel assemblies to be equal to  $10^{-5}$  drops/transfer. This reliability rate is supported by past data from two surveys collected on nuclear plant lifts.

The first survey used is a data set of heavy load lifts that were at least 30 tons. This survey found a total of three drops out of 54,000 (Lloyd 2003). All three drops involved nylon or Kevlar sling failures. Except for the limited number of a specific type of transportation cask (used with Hi-Star DPCs), the lifts that will take place at YM will *not* incorporate slings. It is anticipated that no more than 70 transportation casks of this type will be handled at YM (DOE 2006e).

DOE uses the data in this survey to estimate the probability of failure as,

$$p = \frac{f}{n} \quad \text{Eq.(2)}$$

where  $p$  is the probability of failure,  $f$  is the number of failures, and  $n$  is the number of trials.

If the sling failures are included, then  $p$  is  $3/54,000 = 6 \times 10^{-5}$ . DOE also calculates the failure rate from the data using a noninformative Bayesian prior distribution (NRC 1983),

$$p = \frac{f + 0.5}{n + 1} \quad \text{Eq.(3)}$$

The noninformative prior distribution is a useful approach when there is little data regarding the prior distribution, because it reduces the relative importance of the prior likelihood compared to the data when estimating the posterior likelihood (NRC 1983). Applying this method, DOE estimates the drop rate without sling failures as  $0.5/54,001 = 9 \times 10^{-6}$  (DOE 2006e). The dilemma in using the data from this study is that all the drops

occurred using slings, and only a small percentage of the total number of transfers at YM are expected to employ the use of slings. If the slings are included, the estimate may be too high; if the slings are not included, the noninformative approach must be employed.

Another study cited by DOE in the PHA is recorded handling incidents of a variety of loads (heavy and light) that were caused by equipment failures and/or human error from 1985 to 1999 (BSAIC 2001). This data includes nine drop events out of 1,199,000 transfers. Applying Eq.(3), the probability of failure is  $8 \times 10^{-6}$ . Note that this is a lower rate of failure than the prior survey, even if the three sling failures are *not* included. But, the data mostly consists of assembly transfers, which are lighter than the canister transfers that will take place at YM.

Taking both the data sets into account, the failure ranges from  $8 \times 10^{-6}$  to  $6 \times 10^{-5}$ . DOE considers  $10^{-5}$  an adequate and conservative failure rate for a number of reasons: the cranes will include safety features; lifting operations will be highly controlled; and the use of slings will be limited.

### Number of Transfers

The number of transfers (T) of an item over the emplacement period depends on whether the item is a TAD or a DPC, and if aging is necessary prior to emplacement. The transfers, during which a breach is possible at each of the facilities, are summarized in Table VIII (also described in more detail in Appendix C). Note that TADs and DPCs going to the Aging Facility from the RF or WHF undergo an additional two (2) transfers when they are placed onto and removed from the aging pad. However, the structures, systems, and components that will be used in order to limit the severity of the drop cause

the event sequence to be Beyond Category 2. It should also be noted that since the design is not yet completed, the transfers described below may not reflect the *final* design.

Taking this into account, Utility TADs can undergo up to 6 transfers when a breach is possible: 3 at the CRCF and an additional 3 at the RF if they need to be aged first. Site-specific TADs undergo 7 transfers: 4 at the WHF and 3 at the CRCF. DPCs undergo at most 7 transfers: 4 at the WHF and an additional 3 at the RF if they need to be aged first. Also, there are up to 4 lid transfers where the lid could fall on a DPC causing its breach: 2 at the WHF and an additional 2 at the RF if aging is required.

In summary, the number of transfers of a particular item can be estimated conservatively assuming *every* canister requires aging or by explicitly counting the canisters that need aging. DOE calculates the expected number of occurrences for the drop events assuming every canister requires aging. The waste stream quantities in Table 7, a crane drop rate of  $10^{-5}$ , and a conservative factor of 1.1 “to provide a margin of conservatism and thus increased confidence that the expected number of drops is not underestimated” are applied (DOE 2006e). The deterministic estimates supplied in the PHA are repeated in Table 9.

Table 8

Number of Transfers per Item at Surface Facilities

|      | Number of Transfers per Item |                |          |
|------|------------------------------|----------------|----------|
|      | TAD <sup>a</sup>             | DPC            | Assembly |
| CRCF | 3                            | N/A            | N/A      |
| RF   | 3                            | 5 <sup>b</sup> | N/A      |
| WHF  | 4                            | 6 <sup>c</sup> | 2        |

<sup>a</sup> The TAD has a shield plug that is credited with absorbing the impact energy of a dropped lid so no lid transfers are included in this column.

<sup>b</sup> Vertical DPCs at the RF undergo 3 transfers, horizontal DPCs at the RF undergo 1 transfer, and there are 2 lifts of lids that could cause a DPC breach so 5 total transfers are assumed.

<sup>c</sup> DPCs undergo 4 transfers at the WHF and there are 2 lifts of lids that could cause a DPC breach so 6 total transfers are assumed.

Table 9

## Expected Number of Drops in 50-year Pre-Closure Period

| Item                                     | Number of Transfers/Item | Number of Items | Expected Number of Drops |
|--|--------------------------|-----------------|--------------------------|
| DPC                                      | 11                       | 469             | $5.7 \times 10^{-2}$     |
| Site-specific TAD                        | 7                        | 1,571           | $5.0 \times 10^{-1}$     |
| Utility TAD                              | 6                        | 5,676           |                          |
| Fuel Assembly shipped in bare-fuel casks | 2                        | 21,730          | $4.8 \times 10^{-1}$     |

See Table A-7, A-9, and A-11 of (DOE 2006e). The author has chosen to use the same number of significant figures as is documented in the PHA.

Based on frequencies derived from the OWS, DOE's PHA conducted in March 2006 found *no* Category 1 event sequences and twenty-two Category 2 event sequences (DOE 2006e). However, note that the number of fuel assemblies listed only includes those transferred from *bare-fuel transportation casks*. If the assemblies transferred from *DPCs* are included, the expected frequency is increased to 1.027, classifying the event as Category 1. This oversight is not expected to impact the overall assessment of this event since the dose consequence for the event is within Category 1 *and* Category 2 limits. However, it is useful to analyze the sensitivity of the expected frequencies to changes in operating scenarios since there is uncertainty surrounding the waste stream quantities.

It may be useful to revisit the waste stream quantities in Table 7 considering that over 690 dry storage containers (including DPCs and single-purpose containers) had been loaded at 30 nuclear sites as of December 2004 (NEI 2007). The volume of waste packaged in DPCs is expected to increase in the coming years as spent nuclear pools reach capacity. It is estimated that 20 reactors at 16 sites will need to load additional dry storage by 2010, and at least 22 more reactor sites will increase dry storage by the end of 2015 (NEI 2007). Furthermore, the utilities have little incentive to repackage fuel assemblies currently in DPCs into TADs.<sup>14</sup>

Since the waste stream determines whether events are Category 1 or Category 2, and hence, the regulatory dose limits for those events, there is merit in evaluating the importance of waste stream variations with respect to frequency estimation. Still, in order to gain perspective of the risk, the consequences of these events should be taken into account in addition to their frequencies.

---

<sup>14</sup> Personal communication with Steve Edwards, Spent Fuel Management Progress Energy. January 9, 2007.

### *Consequences of Events*

The consequences of the three events pertaining to this study, as they are defined in the SEIS by DOE, are listed in Table 10. Doses are provided for the maximally exposed off-site individual<sup>15</sup> and the hypothetical worker near the accident, referred to as the *non-involved* worker.<sup>16</sup> A dose is not provided for the involved worker because the structures, systems and components that protect the involved worker reduce the potential for these events to be Beyond Category 2. The NRC has determined that a 30-day exposure period dose is required in the SEIS as opposed to a full year (NRC 2007). Since the PHA doses are based on a one-year exposure period<sup>17</sup>, they are not in exact agreement with the doses listed in the SEIS. However, the differences in the calculated consequences are minimal.

---

<sup>15</sup> The maximally exposed individual is a hypothetical member of the public at the point on the analyzed land withdrawal area boundary who would receive the largest dose from the assumed accident scenario, which is either about 18.5 kilometers (11 miles) southeast of the repository site or 7.8 kilometers (4.8 miles) east of the site.

<sup>16</sup> This non-involved worker is assumed to be 60 meters (180 feet) from the release point.

<sup>17</sup> See Table B-8, Pg. B-15 of the PHA report

Table 10

Dose Consequence per Event

| Event Description                   | Amount of Material at Risk  | Non-Involved Worker TEDE Dose Sv /event (rem/event) (30-day exposure) | Off-site Public TEDE Dose Sv /event (rem/event) (30-day exposure) |
|-------------------------------------|---|---|---|
| Drop with breach of TAD             | 21 PWR or 44 BWR fuel assemblies                                      | $1.0 \times 10^{-2}$  | $6.4 \times 10^{-5}$  |
|                                     |   | $(1.0 \times 10^0)$   | $(6.4 \times 10^{-3})$  |
| Drop with breach of DPC             | 36 PWR or 74 BWR fuel assemblies                                      | $1.7 \times 10^{-2}$  | $1.1 \times 10^{-4}$  |
|                                     |   | $(1.7 \times 10^0)$   | $(1.1 \times 10^{-2})$  |
| Drop with breach of a fuel assembly | 2 PWR or 2 BWR fuel assembly (one drop of an assembly onto the other) | $2.6 \times 10^{-4}$  | $4.6 \times 10^{-6}$  |
|                                     |   | $(2.6 \times 10^{-2})$  | $(4.6 \times 10^{-4})$  |

See Table E-11 of the SEIS (DOE 2002). Consequence estimates are based on the amount of material at risk.

## **Analysis Methodology**

This section provides a brief overview of methodological assumptions used in this chapter to estimate the uncertainty surrounding the frequency of drop events. This includes methods used to generate waste streams and methods used to estimate the likelihood of the number of drop occurrences during the 50-year pre-closure period.

### ***Method to Generate Waste Streams***

The main differences between the approach used in this study and the assumptions in the OWS are summarized in Table 11. The CSNF inventory data used in this analysis differs slightly from that used by DOE for generating the OWS, in that a more recent inventory (2002 instead of 1998) is used, and a variety of pre-closure scenarios are considered. In using the 2002 versus the 1998 data set, the projections of waste discharges may be more accurate. However, since the 1998 and 2002 data set were not compared, the impact of using the more recent database was not evaluated.

Before the repository opens, utilities are assumed to load dry storage when their spent nuclear fuel pools run out of capacity. The TAD is assumed to be available sometime between the years of 2012 and 2020, after which all utilities adopt it for use. One of three orders for the selecting spent fuel assemblies from a facility's pool is applied: (1) oldest fuel first (OFF), (2) youngest fuel first at least five years old (YFF5), or (3) youngest fuel first at least ten years old (YFF10).

Table 11

Comparison of Approaches for Generating Waste Streams

|                               | DOE's 2002 Operational Waste Stream Case B Assumptions | Alternative Modeling Approach        |
|-------------------------------|--|--------------------------------------|
| Inventory of CSNF             | 1998 RW-859  | 2002 RW-859                          |
| Packages                      | Bare-Fuel Casks and DPCs                               | Bare-Fuel Casks, DPCs, and TADs      |
| Zone Loading                  | No   | Yes                                  |
| Short Loading                 | Yes  | No                                   |
| Allocation Trading            | No   | Yes                                  |
| Waste Removal Priority        | Pool   | Pool or Dry Storage                  |
| Dry Canister Removal Priority | N/A  | TADs, DPCs, or a proportional amount |
| Assembly Selection Algorithm  | YFF10  | OFF, YFF10, or YFF5                  |

TADs, DPCs, and bare-fuel transportation casks are expected to accommodate zone loading, meaning canisters are loaded with relatively hotter assemblies in the center and cooler assemblies around the outer perimeter. The 21-PWR and 44-BWR TADs will most likely be designed to hold 9/12, or 20/24 hot/cold assemblies respectively.<sup>18</sup> The per-assembly thermal power output limit for the hotter zone is designed to be twice that of the cooler zone. For example, the per-assembly limits for a 25 kW 21-PWR TAD are 1.67 kW for each of the 9 hotter assemblies and 0.83 kW for each of the 12 colder assemblies. The transportation heat limit is varied from 18kW to 25kW per cask.

After the repository opens (assumed to be sometime between 2020 and 2030), the equivalent of 250 TADs (as some combination of TADs, DPCs and bare-fuel transportation casks) are sent to the repository each year. This rate of shipment is applied to allow for 7,500 TADs to be shipped to YM over 30 years. A DOE study determined the receipt rate of 3,000 MTHM to be approximately equivalent to 250-300 TADs per year (BSAIC 2005d). The shipping campaign could be completed in approximately 24-30 years (DOE 2002). The author has chosen a shipping rate of 250 TAD-equivalents/yr, instead of 300 per year, so that the throughput results can be compared to DOE analyses that apply a 250 TAD-equivalent/yr processing rate (BSAIC 2007b).

In some scenarios, the facilities are assumed to send assemblies from the pool before sending dry storage. In other cases, TADs and DPCs that have already been loaded are sent before removing assemblies from the pools. Three variations of the order in which dry storage is removed are explored: (1) TADs before DPCs, (2) DPCs before TADs, and (3) proportional amounts of TADs and DPCs (e.g., if there are 10 DPCs and 5 TADs on

---

<sup>18</sup> Personal communication with Kris Cummings, Manager DOE Programs, Holtec. July 25, 2007

the storage pad and the facility has allocations for 6 shipments, 4 DPCs and 2 TADs are sent).

A summary of the independent variables (Table 12) and scenarios (Table 13) are provided. Response variables are defined and tracked as a function of the design and operating conditions defined for each scenario. The response variables are the counts of:

- dry storage containers loaded due to lack of capacity in the spent nuclear fuel pools before YM starts to receive waste
- TADs that could potentially be loaded assuming that utilities begin using the TAD as soon as it is commercially available
- shipments arriving above or below the emplacement limit each year
- canisters in the Aging Facility at YM each year
- canisters in the Aging Facility that are thermally cool enough to be removed from the Aging Facility each year

|                         | DPCs before TADs                     | OFF                | R1-R9                 |
|                         |                                      | YFF10              | R1-R9                 |
|                         |                                      | YFF5               | R1-R9                 |
|                         | Proportional amount of TADs and DPCs | OFF                | R1-R9                 |
|                         |                                      | YFF10              | R1-R9                 |
|                         |                                      | YFF5               | R1-R9                 |
| Dry storage before pool | TADs before DPCs                     | OFF                | R1-R9                 |
|                         |                                      | YFF10              | R1-R9                 |
|                         |                                      | YFF5               | R1-R9                 |
|                         | DPCs before TADs                     | OFF                | R1-R9                 |
|                         |                                      | YFF10              | R1-R9                 |
|                         |                                      | YFF5               | R1-R9                 |
|                         | Proportional amount of TADs and DPCs | OFF                | R1-R9                 |
|                         |                                      | YFF10              | R1-R9                 |
|                         |                                      | YFF5               | R1-R9                 |

Upon arrival, waste is assumed to be routed according to the following process flows:

- TADs and DPCs above the thermal limit for emplacement are sent to the Receipt Facility (RF).
- DPCs arriving below the emplacement limit or being removed from the Aging Facility, as well as all bare-fuel transportation casks are sent to the Wet Handling Facility (WHF).
- TADs arriving below the emplacement limit, TADs loaded in the WHF, and TADs being removed from the Aging Facility (AF) are routed to the Canister Receipt and Closure Facility (CRCF).

The process flow assumed in this analysis omits certain paths compared to the flow defined in the SEIS for simplification purposes. The routing paths in the SEIS do not follow explicit rules, and therefore would have required a level of complexity that was not considered necessary for this analysis. The paths that have been eliminated are: cool DPCs or TADs are not routed to the RF, and TADs are not routed *from* the RF *to* the CRCF or from the WHF to the AF. Applying these rules for routing, the handlings required for different types of casks at the surface facilities are tracked to evaluate the potential safety implications of different waste streams.

### ***Method to Estimate Frequency of Drop Events***

The event of a crane drop can be described using a binomial distribution, assuming that the crane lifts are statistically independent, and the chance of failure for each lift is constant. In reality the chance of failure will most likely not remain constant for each lift. The reliability of the crane equipment will change over time depending on the age and

maintenance of the equipment. In addition, human errors will likely decrease as familiarity with the task and equipment increases over time. These two influencing factors may or may not counterbalance each other, but an assumption of constant failure probability is necessary to apply the binomial distribution. The number of transfers can be thought of as the number of trials for the crane to fail, and the probability of  $x$  drops out of a total of  $n$  trials can be described by the probability mass function of a binomial distribution as,

$$P(X = x, n | p) = \binom{n}{x} p^x (1-p)^{n-x} \quad x = 0, 1, 2, \dots, n \quad \text{Eq.( 4)}$$

The change in potential likelihood of the drop frequency can be explored through assuming different parameter values for  $p$  and  $n$ . Instead of *deterministically* calculating the event frequency using a point estimate for the drop rate and the number of transfers as in Eq.(1), the potential *likelihood* of the event frequency is estimated using the probability mass function of the binomial distribution.

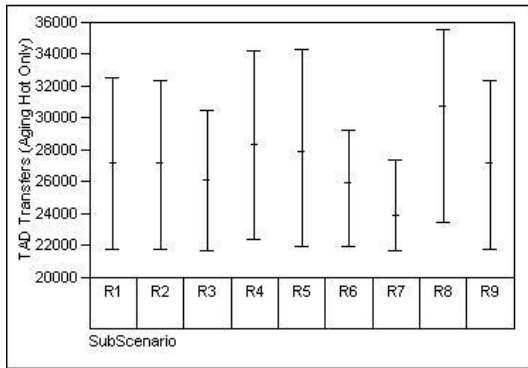

## **Discussion of Results**

Yucca Mountain pre-closure design parameters and waste acceptance operating strategies will impact waste stream characteristics and, therefore, the expected number of times a drop will occur during pre-closure. Since many design and operating parameters are still uncertain, the following results should be used to provide a better understanding of the range of uncertainty associated with the data that support frequency estimates for these events, and not used as an evaluation of the safety of the final design.

### ***Uncertainty Regarding the Number of Transfers***

The number of transfers of assemblies, DPCs, and TADs is calculated for each of the 162 scenarios. Since the 162 scenarios were designed to test the relative impact of each of the subscenario parameters while holding all others at their central value, the scenarios are not randomly sampled, and therefore it is best to use the results to estimate the *range* in the number of transfers, and the relative impact of the independent parameters on number of transfers, and not the particular *distribution* of transfers resulting from the 162 scenarios.

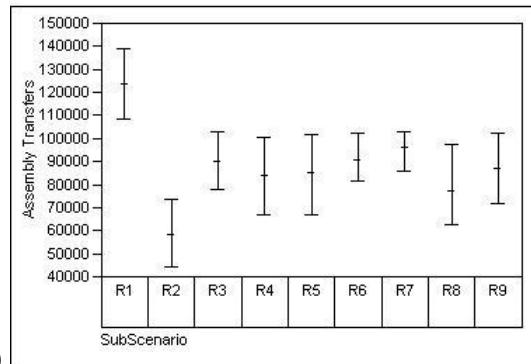

The relative influence of the design and operating parameters on the number of transfers is illustrated through variability charts (Fig. 9). The results are separated into subscenarios R1 - R9 to illustrate the change as each parameter is manipulated from its high to low value. There are nine data points that contribute to the variation of each range bar: three options for dry storage removal priorities multiplied by three options for assembly selection order.

(a)

(b)

(c)

Fig. 9. Variability in the number of item transfers under different scenarios for design and operating conditions: (a) TAD transfers, (b) DPC transfers, (c) assemblies transferred.

Parameters that affect the amount of aging largely contribute to variation in the number of TAD transfers. For example, there is a relatively large difference in the number of transfers between scenarios R7 and R8 (change in thermal limit for emplacement), than from R1 to R2 (change in the year the TAD is available). On the contrary, variation in the number of DPC transfers is driven by the year the TAD is available.

If facilities prioritize shipments from their spent nuclear fuel pools over dry storage, the number of TAD transfers is slightly reduced for many of the subscenarios. This result is not intuitive since much of the waste already in dry storage is older, colder fuel. This result is primarily due to the assumption in the model that utilities use a consistent loading algorithm before and after the repository is open, starting in the year 2002 and the fact that the dry storage data prior to 2002 is not included.

Therefore when utilities load youngest fuel first, most of the packages in dry storage are still above the emplacement limit at the time YM opens. By removing waste from the pool first, the spent fuel already in dry storage at the utility sites cools *at the sites* as opposed to the Aging Facility *at YM*. Therefore, waste that may have required additional transfers by aging at YM is, instead, cooled on the storage pads at the utility sites. In reality, the decision to send canisters from the dry storage facilities before removing waste from the pool may likely have the opposite impact and *decrease* the amount of aging required at YM because utilities have been loading older fuel into dry storage.

When deciding how to prioritize removal of dry storage containers at the facility site, the model assumes facilities choose to send TADs first, DPCs first, or a proportional amount of TADs and DPCs. (Canisters are chosen for shipment on a first in first out

basis within each category.) Removing TADs before DPCs results in a slightly higher number of transfers since a greater number of TADs are aged at YM as opposed to the utility sites. The effect is less apparent when waste is removed from the pool first since most of the waste in dry storage has already cooled below the emplacement limit by the time it is sent to YM. Since all DPCs will eventually be repackaged into Site-specific TADs that are assumed to require 7 transfers regardless of their thermal characteristics, the thermal power output of DPCs arriving at YM does not affect the number of *TAD transfers*.

An important observation is that the scenario resulting in the minimum or maximum number of *TAD* transfers, also results in the minimum or maximum number of *DPC* transfers. Sending older fuel first, allowing for a higher emplacement limit, and enforcing a lower transportation limit reduce the number of TAD transfers because fewer packages require aging. A later opening of the repository allows more time for the waste to cool, reducing the number of TADs that require aging. An earlier availability of the TAD decreases the number of Site-specific TADs (which require more lifts). The scenarios with the maximum and minimum number of transfers are described in Table 14. The range in transfers is summarized in Table 15.

Table 14

Scenarios Resulting in Minimum and Maximum Number of Transfers

| Parameter                     | Minimum Number of Transfers | Maximum Number of Transfers |
|-------------------------------|-----------------------------|-----------------------------|
| Year TAD in Use               | 2012                        | 2020                        |
| Year Repository Open          | 2030                        | 2020                        |
| Transportation Heat Limit     | 18 kW                       | 25 kW                       |
| Emplacement Heat Limit        | 18 kW                       | 11.8 kW                     |
| Waste Removal Priority        | Pool before Dry Storage     | Dry Storage before Pool     |
| Dry Canister Removal Priority | DPCs before TADs            | TADs before DPCs            |
| Assembly Selection Algorithm  | OFF                         | YFF5                        |

Table 15

## Range in Number of Transfers

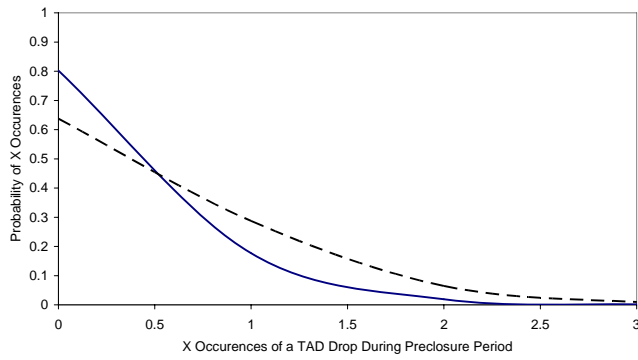

| Variable           | Lower Bound | Upper Bound         |
|--------------------|-------------|---------------------|
| TAD Transfers      | 22,000      | 45,000 <sup>a</sup> |
| DPC Transfers      | 1,000       | 10,000              |
| Assembly Transfers | 20,000      | 140,000             |

<sup>a</sup>This range in transfers does not reflect the range shown in Fig. 9 because it incorporates the possibility that *all* canisters might be aged. For example, if 7,500 TADs are emplaced in YM, there could be as many as 45,000 transfers (six per TAD).

### *Uncertainty Regarding the Frequency of Events*

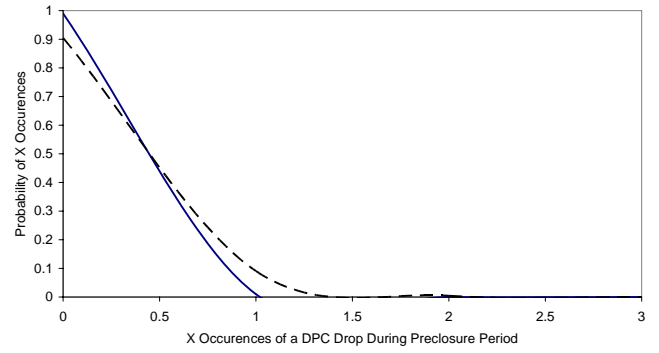

Results in Fig. 10 show that DOE's PHA estimates do not conservatively bound the range of frequencies generated by this study for any of the events. However, DOE's point estimates do fall within the likely area of the distributions. DOE's estimates are not conservatively bounding primarily because the author considered scenarios with more than 469 DPCs. Still, even taking into account the upper range in number of transfers that could occur, the events are likely to be Category 2 or Beyond Category 2. For example, the probability that the number of assembly drops is less than or equal to one using the binomial distribution in Fig. 10(c), is 0.98 in 20,000 transfers and 0.84 in 140,000 transfers.

Additional variation in the event frequency can be explored by changing the crane drop rate assumptions. As seen in Fig. 11, increasing the drop rate to be  $6 \times 10^{-5}$  alters the shape of the distributions for the number of event occurrences. This crane drop rate corresponds to the survey that found 3 failures of the slings in 54,000 trials, and is most likely an overly conservative drop rate since slings will not be used for the most part at YM. While the chances of the events being classified as Category 1 are greater with this increase in the drop rate, one needs to keep in mind the consequences resulting from a single occurrence and how they relate to the regulatory limits.

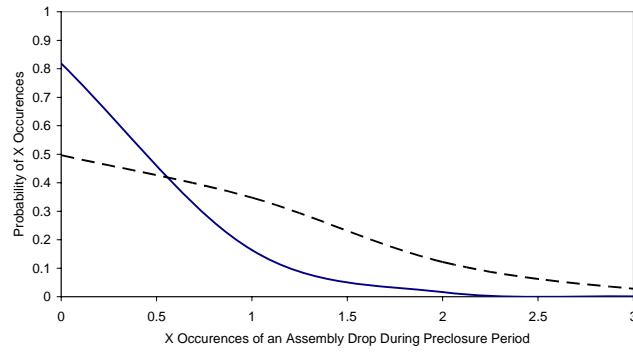

— 22,000 Transfers Drop Rate of  $1e-5$   
 - - 45,000 Transfers Drop Rate of  $1e-5$

(a)

— 1,000 Transfers Drop Rate of  $1e-5$   
 - - 10,000 Transfers Drop Rate of  $1e-5$

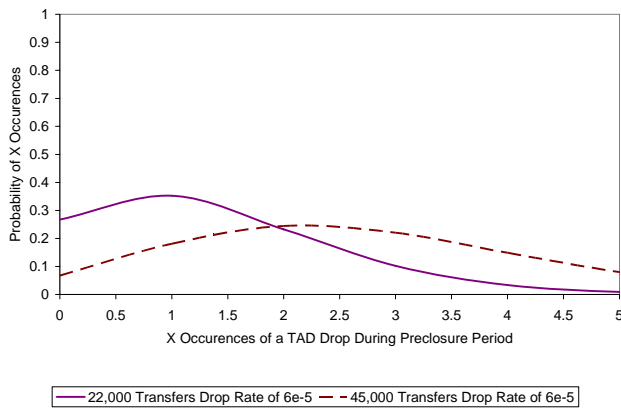

(b)

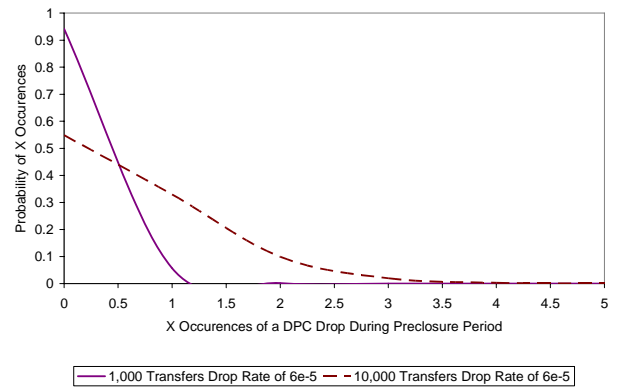

— 20,000 Transfers Drop Rate of  $1e-5$   
 - - 140,000 Transfers Drop Rate of  $1e-5$

(c)

Fig. 10. Expected number of occurrences of a drop over the 50-year pre-closure period assuming a crane drop failure rate of  $1 \times 10^{-5}$ : (a) TAD, (b) DPC, and (c) bare-fuel assembly.

(a)

(b)

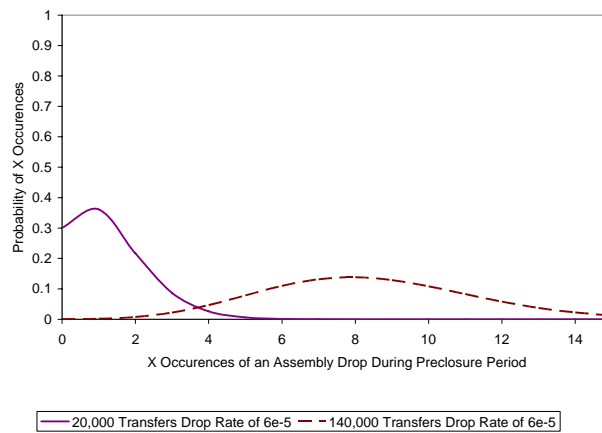

Fig. 11. Expected number of occurrences of a drop over the 50-year pre-closure period assuming a crane drop failure rate of  $6 \times 10^{-5}$ : (a) TAD, (b) DPC, and (c) bare-fuel assembly. Note the change in x-axis in (c).

If these events were determined to be Category 1 (expected frequency  $\geq 1$ ), as opposed to Category 2 (expected frequency  $< 1$  but  $\geq 10^{-4}$ ), DOE would need to show that the dose consequence meets the Category 1 limits of no more than .05 Sv (5 rem)/yr to workers, no more than 0.15 mSv (15 mrem)/yr to the off-site public, and no more than 1 mSv (100 mrem)/yr to the on-site public. It might also be considered that the non-involved worker doses for dropping a single TAD or DPC both exceed the 5 mSv (500 mrem)/yr ALARA goal.

Although the consequences are within Category 1 *and* Category 2 limits for a single occurrence of all three events, one should consider the assumptions that went into determining these doses. For example, there is potential for the breach of a TAD or DPC, if unmitigated, to result in an offsite dose consequence that could exceed the performance requirements of 10 CFR § 63 due to the oxidation of damaged fuel assemblies. Therefore, DOE takes credit for HEPA filters when calculating this dose estimate to ensure that the offsite dose remains within allowable limits (DOE 2006e).

Also, one should consider that the consequences are listed per event and the requirements are in yearly doses. The worker dose consequence of a *single* TAD drop of 0.01 Sv (1 rem) is within the Category 1 dose limit of 0.05 Sv (5 rem)/yr for workers. Also, the public dose consequence for a single TAD drop of  $6.4 \times 10^{-2}$  mSv (6.4 mrem) is within the limit of  $1.5 \times 10^{-1}$  mSv (15 mrem)/yr. It is clear that the consequences for this event do not exceed the dose limits for Category 1, but it is difficult to compare a dose consequence for *one event* with a requirement over the time span of *one year*. For example, since the consequence to off-site public of dropping one TAD is about half the regulatory yearly dose limit, more than two TADs would have to be dropped in a single

year in order to exceed the off-site *public* dose limit. Five or more TADs would have to be dropped in a single year in order for the expected dose consequence to exceed the Category 1 limit for *workers* of 0.05 Sv (5 rem)/yr.

The same calculations can be made regarding the drop of a DPC canister or an assembly. If three or more DPCs are dropped in a single year, the regulatory limit for workers of 0.05 Sv (5 rem)/yr may be exceeded. If more than one DPC is dropped in a single year, the consequence would exceed the Category 1 limit for public. More than approximately 190 assemblies would have to be dropped to exceed the worker limit and more than about 30 assemblies would have to be dropped to exceed the off-site public limit. A summary of the number of events that would need to occur in a single year in order to exceed the Category 1 dose limits is provided in Table 16.

Table 16

Number of Events Needed to Occur in a Single Year for the Dose Consequence to Exceed Category 1 Limits

| Event Description                   | TEDE Dose Consequence Sv /event |                      | Number of Events Needed to Occur in a Single Year for Dose to be $\geq$ Category 1 Limit |                 |
|-------------------------------------|---------------------------------|----------------------|--|-----------------|
|                                     | Non-Involved Worker             | Off-site Public      | Non-Involved Worker  | Off-site Public |
| Drop with breach of TAD             | $1.0 \times 10^{-2}$            | $6.4 \times 10^{-5}$ | 5  | 3               |
| Drop with breach of DPC             | $1.7 \times 10^{-2}$            | $1.1 \times 10^{-4}$ | 3  | 2               |
| Drop with breach of a fuel assembly | $2.6 \times 10^{-4}$            | $4.6 \times 10^{-6}$ | 190  | 30              |

See Table E-11 of the SEIS (DOE 2002) for consequence estimates. Consequence estimates are based on the amount of material at risk.

As stated, at least three TADs would need to be dropped in a single year in order to exceed the Category 1 limit for the *public*; at least five drops would have to occur in a single year in order to exceed the Category 1 limit for *workers*. In a single year, the number of trials for a TAD is in the range of 250-300. The chance of *more* than 3 events occurring  $P(X > 3) = 1 - P(X \leq 3)$ . The probability of less than three TADs dropping in a single year  $P(X \leq 3)$  can be found by integrating the probability mass function, or directly by using the binomial cumulative distribution function. For example, assuming a drop rate of  $6 \times 10^{-5}$  and 300 trials in a single year,  $P(X \leq 3) \approx 1$ , so  $P(X > 2) \approx 0$ . This type of analysis can be also shown for  $x$  occurrences of DPC drops and assembly drops occurring in a single year and is a useful way to communicate the potential frequency of the events.

## **Conclusions and Recommendations**

This chapter reviews the basis for DOE's waste stream assumptions in the *Preliminary Hazards Analysis* for pre-closure operations. The review is an exercise that brings to light the tendency for extensive projects drawn out over long periods of time to grandfather past analyses, assumptions and data, often without considering the benefits that could be gained from a renewed approach. Although a number of possible waste streams were originally generated by DOE, only a single variation of one (Case B of the OWS) was carried forward. After which, point estimates of items contained in the OWS were used to estimate the frequency of three internal pre-closure events.

The following insights can be drawn from this research:

- TADs and DPCs that need to be aged require more crane transfers than those that do not. Therefore, the scenarios that require less casks to be aged (e.g.,

oldest fuel first and/or higher emplacement limit scenarios) also require less expected total package handlings.

- Scenarios that contained fewer DPCs resulted in lower frequencies of dropping a DPC *or* a TAD because TADs that are loaded at YM potentially require more transfers than TADs loaded at the utility site.
- Although DOE applied a conservative approach in assuming every package will require aging, the estimates did not conservatively bound the frequencies generated by this analysis. This is a result of using a single waste stream and crane drop rate in a deterministic function for calculating the number of occurrences.

Since the number of TAD transfers, the number of assembly transfers, and the number of DPC transfers all increase with the number of DPCs and bare-fuel casks, DOE may want to reconsider the number of DPCs assumed in the waste stream. Accurately estimating the number of bare-fuel transportation casks or DPCs in the waste stream is difficult because of the variety of DPC sizes that exist, and the unpredictability regarding which DPCs may be repackaged into TADs at the utility sites. Because DPCs are already on the storage pad of the waste generators, there seems little reason to move them in order to store them *again* at YM. By negotiating agreements that reduce the number of DPCs that need to be aged and repackaged at YM, DOE could reduce the potential frequency of a canister drop.

Still, DOE estimates were within the likely range of frequencies that was generated in this analysis. And, the consequences of these events are low enough that their categorizations will not likely impact the ability to meet regulatory requirements,

(provided that the assumptions regarding the systems structures and components relied upon for the dose estimates, such as the HEPA filter, are reasonable). Considering the inconclusiveness surrounding future waste schedule negotiations, DOE could strengthen its PHA by adopting a probabilistic approach to estimating the frequencies of the drop events. This would help to communicate the risk posed by the events, and allow for an analysis that is less reliant on deterministic estimates for waste stream quantities and crane drop rates.

## CHAPTER IV

### SURFACE FACILITY THROUGHPUT WASTE STREAM VARIATIONS

#### Abstract

This chapter also focuses on the impact of waste stream variations on throughput during pre-closure operations at the proposed repository for high-level waste at Yucca Mountain (YM), NV (Spradley, Abkowitz and Clarke 2008; Appendix D). The objective of the research is to gain a better understanding of how waste stream variations affect surface facility throughput, defined as the rate at which packages are prepared for aging or emplacement in the surface facilities at YM. The basis for, and adequacy of, the current surface facility throughput requirements are reviewed by evaluating throughput performance subject to various waste stream scenarios.

Results indicate that, under most scenarios, DOE's design adequately accommodates the *mean* demand over the operating lifetime for the Canister Receipt and Closure Facility (CRCF) and Receipt Facility (RF), but not the Wet Handling Facility (WHF). Pending future negotiations between the waste generators and DOE, the WHF capacity may need to be increased in order to efficiently handle assemblies arriving in Dual-Purpose canisters (DPCs) or bare-fuel transportation casks. DOE should strive to negotiate schedules that uniformly distribute shipments of DPCs and avoid shipments of very hot DPCs, so the WHF might be able to handle *all* incoming DPCs and bare-fuel casks.

Results also show a high potential for variability in annual throughput demand at the CRCF and RF that might result in system backups. In the event of bottlenecks, underused facilities may need to fulfill functional roles of those that are over-burdened. The over-lap of functional capability confuses design goals for the system. An alternative design is proposed that is based on functional goals of the facilities as opposed to the buildings themselves, along with other recommendations.

## **Introduction**

### ***Yucca Mountain Pre-Closure Waste Management System***

The U.S. Department of Energy (DOE) is currently designing a geologic repository for the nation's high-level nuclear waste (HLW) at Yucca Mountain (YM), NV. The plan for the repository can be categorized into two temporal phases: pre-closure and post-closure. During pre-closure, the waste is transported to YM, processed at the YM surface facilities, and emplaced in the repository. After all the waste has been emplaced, the drifts will remain open and will be monitored for up to 300 years before the repository is to be closed.

Construction of the repository will not be fully complete before shipments of waste commence. Instead, DOE is planning a phased approach to constructing surface facilities and excavating repository drifts. Waste will be shipped over an approximately 25 to 30-year time period and emplacement activities may continue for up to 50 years following the opening of the repository.. Emplacement rate is not expected to keep up with the

shipment arrival rate due to the pace of drift excavation, as well as thermal constraints, which may delay emplacement. The thermal management strategy requires each waste package to be below a specified thermal energy (kW) before it can be emplaced. Waste that does not meet the criteria will be aged above ground at YM until it cools.

A recent design change calls for approximately 90% of the commercial spent nuclear fuel (CSNF) to be packaged at the utility sites in canisters that can be used for transport, aging, and disposal (TAD). This comprises roughly 80% of the entire 70,000 metric tons of heavy metal (MTHM) destined for YM since CSNF makes up 90% of the waste stream. The remaining 10% of CSNF will be shipped either in transportation casks carrying bare-fuel assemblies or in Dual-Purpose casks (DPCs). Upon arriving at YM, waste will be prepared for emplacement or aged at the surface facilities. Under the new design, routing of CSNF at the repository site will be primarily governed by its thermal characteristics, whereas prior to this decision, thermal characteristics were not as critical of a driver. This is because, prior to the design change, DOE had the opportunity to co-mingle hot and cold assemblies to meet thermal limits.

### ***Surface Facility Process Flow***

The surface facilities at the repository will be used for the following functions as defined in the SEIS:

- The Initial Handling Facility (IHF) will receive DOE HLW and Naval spent nuclear fuel, and prepare it for emplacement.
- The Canister Receipt and Closure Facility (CRCF) will transfer TADs from transportation overpacks to disposal overpacks, but will also be able to

transfer TADs or DPCs to aging overpacks to be sent to the Aging Facility. In addition, the CRCF could be used for transferring DOE HLW and SNF canisters to disposal packages. The disposal overpacks that have been loaded with canisters will be welded at the CRCF. DOE plans to construct as many as three CRCFs in a phased approach.

- The Wet Handling Facility (WHF) will receive DPCs and bare-fuel transportation casks. Each DPC or bare-fuel transportation cask will be placed in a pool and the assemblies within it will be transferred to a TAD. Then, the TAD will be removed from the pool, placed in the appropriate overpack, and sent to the CRCF or the Aging Facility.
- The Receipt Facility (RF) primarily will function to receive TADs or DPCs that are too hot to be emplaced and transfer them into aging overpacks to be sent to the Aging Facility. However, the RF also can be used to handle canisters that are cool enough to be emplaced, but nevertheless require storage due to bottlenecks in the CRCF. *(Note that the RF design is very similar to the CRCF absent the capability to weld disposal overpacks.)*

The receipt rate of YM will ramp up during the first 5 years. The initial operating capability (Year 1) commences when the IHF, CRCF-1, and WHF are fully constructed. The RF will come on-line at the start of Year 2, CRCF-2 at the start of Year 4, and CRCF-3 at the start of Year 5 (DOE 2006a). Once the third CRCF is on-line, the repository is expected to have sufficient capacity to handle a steady-state rate of 3,000 MTHM (Table 17). The receipt rate ramp-up assumptions originally formed the basis for surface facility throughput criteria.

Table 17

Receipt Rate for Yucca Mountain

See Ref. (DOE 2006a)

## **Research Objectives**

This research aims to gain a better understanding of the surface facility throughput performance through the following objectives:

- Review the waste stream assumptions made by DOE in the basis for the surface facility throughput capacity.
- Generate multiple waste streams, as a function of repository design parameters and operating strategies, in order to estimate the variability in demand for the surface facilities at YM.
- Evaluate the ability of the current design to meet estimated demand.
- Provide recommendations for possible improvements to the current design.

## **Review of DOE Surface Facility Criteria**

### ***Initial Throughput Criteria***

Initial throughput criteria, in terms of MTHM/yr for each facility, are documented with the TAD-based repository design (BSAIC 2006). As shown in Table 18, the original goals afforded a wide contingency margin by designing the facilities with nearly 100% excess capacity over the steady-state receipt rate.

The basis for these initial requirements was as follows (BSAIC 2006):

- Year 1 is not used as a driving factor because only 400 MTHM are expected.

The sum of waste received during Years 2-4 is used as a starting point for

design since this amount (3,800 MTHM) is close to the steady-state receipt rate.

- CRCF-1 is required to operate alone for the entire 3 years from Year 2-4 even though CRCF-2 will come on-line by Year 4, and the 3,800 MTHM will not be *entirely* commercial waste. Dividing 3,800 MTHM by 3 years equates to 1,267 MTHM/yr for CRCF-1. In the steady-state years, the remainder of 3,000 MTHM minus 1,267 MTHM, or 1,733 MTHM, is split between CRCF-2 and CRCF-3 (867 MTHM/yr each). This requirement could be thought of as inconvenient since it calls for CRCF-2 and CRCF-3 to be a different size than CRCF-1. Furthermore, it could be construed as overly conservative to design the three CRCFs to process 25% more than the steady-state receipt rate when a portion of the 3,000 MTHM is likely to be routed to the RF and WHF.
- The WHF must be capable of processing 10% of the 3,000 MTHM (300 MTHM) that will not arrive in TADs, and instead will arrive either in bare-fuel transportation casks or in DPCs. This is based on the assumption that DOE is able to reach agreements with the utilities regarding what DPCs will be included in the waste stream, ensuring that non-TAD packaging will constitute no more than 10% of all shipments.
- The RF is expected to process fully 90% of the 3,000 MTHM (2,700 MTHM) that is anticipated to arrive within TAD canisters. Again, it could be construed as overly conservative to design the RF to process the entire TAD-waste stream when a portion of TADs are likely to be routed to the CRCF.

The criteria in Table 18 were not adopted because excess capacity during the ramp up and steady-state years was considered unnecessarily large. The study states that “while some design margin in terms of excess capability is desirable and even necessary, this 200% and 100% excess capacity is much more than may be needed.”(BSAIC 2007b) Therefore, new throughput goals were defined to reduce excess capacity to a more reasonable range of 10%-50% (BSAIC 2007b). A study defining new criteria, *Nuclear Facilities Receipt Rate Requirements Analysis Engineering Study*, considers a variety of scenarios, including ranges in thermal characteristics of TAD canisters. Still, the general approach taken isolates each facility as opposed to considering them as an interconnected system. Also, *all* alternative scenarios are based on a *single* case of the 2002 Waste Stream Projections Report, which limits the robustness of the study.

Table 18

Initial Surface Facility Performance Requirements for TAD Concept

|                                  | Year 1 | Year 2 | Year 3 | Year 4 | Year 5 + |
|----------------------------------|--------|--------|--------|--------|----------|
| Quantity Received CSNF (MTHM/yr) | 400    | 600    | 1,200  | 2,000  | 3,000    |
| Processing Capacity              |        |        |        |        |          |
| CRCF-1                           | 1,267  | 1,267  | 1,267  | 1,267  | 1,267    |
| CRCF-2                           | 0      | 0      | 0      | 867    | 867      |
| CRCF-3                           | 0      | 0      | 0      | 0      | 867      |
| WHF                              | 300    | 300    | 300    | 300    | 300      |
| RF                               | 0      | 2,700  | 2,700  | 2,700  | 2,700    |
| Total Capacity                   | 1,567  | 1,567  | 4,267  | 5,134  | 6,000    |

Significant figures are consistent with those provided in DOE documents (BSAIC 2006).

### ***New Throughput Criteria***

The design for steady-state operations recommended by the *Nuclear Facilities Receipt Rate Requirements Analysis Engineering Study* is outlined in Table 19 (BSAIC 2007a). As seen, much of the excess capacity is eliminated, but the logic behind this set of more complicated requirements is debatable. The following discussion takes the reader through DOE's assumptions in developing the new criteria.

The 2002 Operational Waste Stream (OWS) is used in conjunction with the receipt rates for YM as a basis for the new requirements. Since the OWS was defined prior to the TAD design change in 2006, the waste stream did not include TADs. Instead, the OWS consists of bare-fuel rail shipments, legal weight bare-fuel truck shipments, and DPC rail shipments (BSAIC 2003). The bare-fuel rail shipments were assumed to be arriving as TADs, but no other adjustments were made to the OWS in applying it to the new criteria. This implies that DOE assumes that the DPCs and bare-fuel truck casks included in the OWS are not impacted by the decision to use the TAD.

### ***Wet Handling Facility***

In order to define the expected demand on the WHF, DOE looked back at the distribution of annual rates of legal weight bare-fuel truck casks and DPCs documented in "Case B" of the OWS. The 4<sup>th</sup> highest peak from each distribution was chosen as a reasonable design goal for processing bare-fuel truck casks and DPCs. This equates to 140 bare-fuel truck casks (~230 MTHM) and 26 DPCs (~286 MTHM). (Note that the highest peak from each distribution was 167 bare-fuel casks and 36 DPCs, respectively.)

DOE judged 26 DPCs/yr as exorbitant for the WHF because a portion of the DPCs are expected to be too hot to be sent directly to the WHF and must be aged at YM instead.

Since the previously defined criterion for the WHF was only 300 MTHM, the study concludes that the remainder after accounting for the 230 MTHM in bare-fuel truck casks (70 MTHM) was a sufficient DPC capacity for the WHF. The 70 MTHM is rounded up to 77 MTHM to be adequate for processing 7 DPC at 11 MTHM per DPC. The basis for deciding that each DPC is 11 MTHM is not explained. In other studies, DOE has assumed that DPCs contain at most 36 PWR or 74 BWR assemblies and assemblies weigh on average 425 kg (PWR) or 175 kg (BWR). This leads to concluding that larger PWR and BWR DPCs weigh 15 or 13 MTHM, respectively. Applying these same assumptions, DPCs weighing 11 MTHM would carry 25 PWR or 63 BWR assemblies. An estimate of 11 MTHM per DPC may be reasonable, but seems superfluous to add 7 MTHM to the criteria just so it is divisible by 11, considering the uncertainty surrounding the size of DPCs.

### ***Canister Receipt and Closure Facility***

Given that 300 MTHM of the 3,000 MTHM is allocated to the WHF, the remaining 2,700 MTHM is split between three CRCFs and the RF. The method of allocating the remaining 2,700 MTHM among three CRCFs and the RF is derived from the assumption that 50% of the waste will arrive above the thermal emplacement limit of 11.8 kW (referred to as “hot”). One might expect that the entire portion assumed to be arriving in hot TADs ( $0.5 \times 2,700 \text{ MTHM} = 1,350 \text{ MTHM}$ ) would be routed to the RF and the remainder to the CRCFs. However, the study concludes that only 70% of the 1,350

MTHM, or roughly 1,000 MTHM, is routed to the RF. This is because there are three CRCFs and only one RF in the design, and DOE states it would not be rational to set the criteria for *one* RF equal to that of *three* CRCFs.

Requiring three CRCFs poses a “chicken or an egg” type of dilemma. It begs the question of whether the decision for three CRCFs was made *before* the design requirements were established. Why should the design be based on the premise that there will be three CRCFs? Typically, one would demonstrate a *need* for the number of CRCFs to be built by analyzing the expected total CRCF demand and a reasonable capacity for a building like a CRCF. Also, in determining the goals for the CRCFs, DOE neglected to account for use of the RF for transferring TADs into disposal overpacks. The capacity of the RF in relation to the CRCF is especially important after the shipping campaign has ended because the RF will no longer be needed to receive waste. Thus, the RF capacity for transferring canisters could supplement the CRCF capacity.

In addition to the 1,000 MTHM of hot TADs, the RF is required to have capacity for DPCs that are too hot to be routed to the WHF. Following the same rationale used for TADs, approximately one-half of the DPCs would fall into this category. Instead of using the 4<sup>th</sup> highest peak (26 DPCs) of the distribution generated in Case B of the OWS as an upper bound for the number of DPCs arriving in a given year (as was done for the WHF), DOE uses the highest peak of 36 DPCs (396 MTHM).

The same logic used for TADs is also applied for DPCs in that only 70% of the “hot” DPCs are routed to the RF, resulting in a criteria of 140 MTHM (396 MTHM \* 50%\*70%) of DPCs. The goal of 140 MTHM is rounded up to 150 MTHM for reasons

unstated. The incorporation of a 10% buffer is an example of an arbitrary conservatism with little clarification of how it may improve the ability to reach design goals.

TADs that are less than 11.8 kW (1,350 MTHM) are split between the three CRCFs (450 MTHM each). In addition, hot TADs that were *not* routed to the RF are sent to the CRCFs. However, the study adds a 10% buffer, assuming that 40% (as opposed to 30%) of the hot 1,350 MTHM (~600 MTHM) are sent to the CRCFs (200 MTHM each). Applying this logic to DPCs, 40% of hot DPCs are sent to the Aging Facility via one of the CRCFs ( $396 \text{ MTHM} * 50\% * 40\% = 79 \text{ MTHM}$ , rounded up to 90 MTHM, or 30 MTHM for each CRCF). A few of the cooler DPCs (20 MTHM in each CRCF) are added to the expected demand for each CRCF because the RF or WHF are not expected to be able to accommodate them. This yields a total capacity of 50 MTHM in DPCs for each CRCF.

The criteria are summarized in Table 19 in terms of MTHM. The criteria have also been converted to units of TADs, DPCs, or bare-fuel assemblies. This conversion required assuming the ratio of BWR to PWR TADs arriving each year, as well as the size of DPCs that are used. Assuming DPCs carry 36/74 PWR/BWR assemblies and half the containers are PWR while the other half are BWR, facilities should be able to process approximately 420 TADs per year.

Table 19

## New Surface Facility Performance Requirements for TAD Concept

| ITEM                             | WHF  |            |             | 3 CRCFs |              | RF    |              | TOTAL |                  |
|----------------------------------|------|------------|-------------|---------|--------------|-------|--------------|-------|------------------|
|                                  | MTHM | Assemblies | TADs Loaded | MTHM    | TADs or DPCs | MTHM  | TADs or DPCs | MTHM  | TAD - Equivalent |
| Bare CSNF                        | 230  | 770        | 30          | N/A     | N/A          | N/A   | N/A          | 230   | 30               |
| DPCs                             | 77   | 250        | 10          | 150     | 10           | 150   | 10           | 377   | 40 <sup>a</sup>  |
| TADs < Thermal Emplacement Limit | N/A  | N/A        | N/A         | 1,350   | 160          | N/A   | N/A          | 1,350 | 160              |
| TADs > Thermal Emplacement Limit | N/A  | N/A        | N/A         | 600     | 70           | 1,000 | 120          | 1,600 | 190              |
| TOTAL                            | 307  | 1,000      | 40          | 2,100   | 250          | 1,150 | 130          | 3,557 | 420              |

Assumes 50% of the assemblies arrive as PWR and 50% as BWR, significant figures for MTHM are the same as DOE's, number of assemblies and canisters are rounded to the nearest ten.

<sup>a</sup> DPCs are converted to TAD-equivalents, causing the total to be slightly greater than the sum across all columns

### *Analysis of New Criteria*

The rationale behind some of the conjectures in the new design, mainly the routing of DPCs to the CRCF or the RF and the presupposition that 50% of the waste will be below the thermal emplacement limit any given year, merits further investigation.

#### Routing of Dual-Purpose Canisters

The original purpose of the CRCF *does not* include handling DPCs (DOE 2002). DPCs come in a variety of shapes and sizes and some may require special pedestals for movement into the transfer pit of a facility. They are also expected to constitute less than 10% of the entire waste stream (BSAIC 2007e). This provides motivation to *limit the number of facilities that are required to handle DPCs* - not complicate the surface facility design by expecting the RF, WHF, and three CRCFs *all* to be able to process DPCs.

The necessity of aging DPCs at YM is also debatable. It seems redundant to age *any* of the DPCs at the repository surface considering DPCs are *already* on the aging pads at the facilities, and most contain older spent nuclear fuel. Waste generators are expected to send waste from their spent nuclear fuel pools *prior* to removing waste that is already in dry storage containers in order to free up space in the pools, so it is reasonable that they would be amenable to staggering DPC shipments. As is demonstrated in Chapter 3, aging DPCs at YM requires extraneous material transfers that could be avoided.

A better approach may be to design the WHF to accommodate *all* the DPCs arriving each year. This could be achieved if the rate of DPC arrival is somewhat uniformly spread over the entire shipping campaign. That way, the design for the WHF can be kept at a reasonable capacity, while still maintaining the ability to process all DPCs and bare-fuel casks in the WHF immediately upon arrival. The upstream impact of this will

depend on the willingness of the utilities to stagger shipments of their DPCs. If the utilities do not have an urgency to remove all their DPCs from the dry storage pads first, but also do not desire to leave the DPCs until the end of the queue, then it is reasonable that they would stagger the shipments of dry storage with shipments from the pool.

### Thermal Characteristics of Waste Stream

Another major supposition applied by DOE for determining the new throughput design is that a maximum of 50% of TADs will arrive with a thermal power greater than 11.8 kW (BSAIC 2007a). The basis of this assumption is an extrapolation of data generated by a particular case of the OWS (BSAIC 2003). The study acknowledges that the specific thermal outputs of the waste stream are not easily predicted, but rationalizes a 50/50 split since the mean thermal output of the assemblies in the entire waste stream is near the value that would be necessary for 11.8 kW TAD canisters. It also concludes that, even though it would be *possible* for all or none of the waste arriving in a given year to be greater than 11.8 kW, neither of these possibilities is reasonable.

We argue that it is not only reasonable, but quite suitable to consider more or less than 50% of the waste stream arriving at a thermal power greater than 11.8 kW. The number of TADs that arrive above or below the emplacement thermal limit will vary from year to year depending on the order of waste acceptance (e.g., oldest fuel first vs. youngest fuel first) and operating design parameters (e.g., transportation or emplacement heat limit). Also, the OWS was developed prior to the TAD decision, which is likely to impact the thermal characteristics of the waste packages. This provides motivation for analyzing potential throughput under various YM pre-closure scenarios.

The remainder of this chapter describes the method used to estimate potential variations in annual demand at surface facilities, assuming a variety of design and operating scenarios. Conclusions are drawn regarding how waste stream variations impact expected surface facility throughput.

### **Analysis Methodology**

An overview of the data and assumptions applied for this research are provided in this section. CSNF inventory data was taken from the RW-859 2002 Database, supplied by the Energy Information Administration. Dry storage loaded prior to 2002 (approximately 4,200 MTHM) is not included in the inventory because data describing the contents of individual dry storage containers at each site was not available. Because this is a small relative volume compared to 63,000 MTHM, and primarily consists of older fuel, the omission of this data does not preclude the ability to produce meaningful results. However, the reader should take into consideration that the results provided do not include the DPCs or SPCs loaded prior to 2002, and therefore most likely *underestimate* demand on the WHF.

The model generates waste streams following one of three utility waste shipment orders: oldest fuel first (OFF), youngest fuel first at least 10 years old (YFF10), and youngest fuel first at least 5 years old (YFF5). A variation on waste shipment order includes giving priority to dry storage over fuel assemblies in the pool or vice versa. The trading of allocations among waste generators is permitted in order to achieve a better understanding of potential bounding thermal characteristics in the youngest fuel first scenarios. Uncertainty in the following design parameters and time-lines is also explored:

transportation heat limit, emplacement heat limit; the year the TAD is placed into use; and the year of initial steady-state operating capability at YM. Finally, sensitivity analyses are conducted by varying the continuous parameters to their minimum or maximum values from their mean. The independent variables and scenarios defined are the same as those in Chapter 3, and can be reviewed in Table 12 and Table 12.

Annual demand on the surface facilities is estimated according to the following process flows:

- TADs and DPCs arriving above the thermal emplacement limit are sent to the Receipt Facility (RF).
- DPCs arriving below the thermal emplacement limit or cool enough to be removed from the Aging Facility, as well as all bare-fuel transportation casks, are sent to the Wet Handling Facility (WHF).
- TADs arriving below the thermal emplacement limit, TADs loaded in the WHF, and TADs cool enough to be removed from the Aging Facility (AF) are routed to one of the Canister Receipt and Closure Facilities (CRCF).

The process flow assumed in this analysis omits certain paths compared to the flow defined in the SEIS for simplification purposes. Specifically, cool DPCs or TADs are not routed to the RF, and TADs are not routed from the RF to the CRCF. Of course, if the CRCF is overwhelmed, cool packages *could* be routed to the RF and aged instead of being emplaced. Similarly, if bottlenecks occur in the WHF, DPCs that are below the thermal emplacement limit could also be sent to the Aging Facility via the RF. However, this would require additional handling and storage of waste that would not be necessary if the capacity of the surface facilities was designed around the waste stream.

On the other hand, scenarios in which a majority of the waste arriving is *above* the thermal emplacement limit will quickly saturate the RF throughput capacity and leave the CRCF with very little demand. In this case, the CRCF could act as an RF by placing canisters in aging overpacks. Still, this is not necessarily desirable because the CRCF is *primarily* intended to transfer canisters to disposal overpacks and weld them. Hence, utilizing the CRCF for merely transferring canisters to aging overpacks could be considered a misuse of expensive welding capacity. Wet storage capacity in the WHF may also be able to offset backups in the RF by allowing for the co-mingling of assemblies from hotter DPCs with cooler ones. However, this may be difficult since wet storage capacity in the WHF is limited to only 200 fuel assemblies (BSAIC 2007e). DOE's ability to handle very hot DPCs in the WHF will also be constrained by the necessary cooling of DPCs before they can be filled with borated water (BSAIC 2007e).

Even with these conceivable overlapping functions of the surface facilities, the model used in this analysis does not reroute waste. This was necessary for the modeling to be tractable, but is also useful for isolating demand associated with *thermal constraints* so it can be compared with the current design. Applying these rules for process flow, the annual demand at each of the surface facilities is recorded to evaluate the throughput implications of different waste streams.

Response variables include:

- Annual demand in number of canisters for the RF and CRCF.
- Annual demand in number of DPCs and number of assemblies for the WHF.
- Annual variability in demand for all facilities.
- Number of canisters in the Aging Facility each year.

## Discussion of Results

The first question addressed was if DOE's surface facility design capacity was adequate to meet the *mean* demand over all operating years in the scenarios that were explored. Because the model used in this analysis does not re-route waste in the event of an overflow, there were many years in which the RF was over utilized and the CRCF was not used, or vice versa. This absence of re-routing may artificially skew averages of demand distributions because there is uncertainty regarding the extent to which facilities will be used to perform the roles of other facilities. In attempt to understand the implications of facility role substitution on averaging results, results are summarized in two ways: (1) annual demand for the years of operation including years in which the facility is not utilized, and (2) annual demand from this same time period *only* including years in which the facility is utilized. Both summaries of the results are within the design criteria for the CRCF and outside the design criteria for the WHF under most scenarios, so only the latter summary of the results is shown in the figures. Subtle differences in data summaries with respect to the RF are explained further in this discussion.

A variability chart for each facility (Fig. 12 - Fig. 16) gives a sense for the demand in a given scenario. The scenario mean values are connected (jagged horizontal line) and a reference (straight horizontal line) indicating DOE's throughput capacity is drawn so that the mean demand can be easily compared with capacity. The lower portion of each chart reveals which parameter has the largest *impact on the annual variability* of demand by looking at the change between the even and odd scenario numbers.

### *Canister Receipt and Closure Facility*

The average demand at the CRCF is well below DOE's criteria (250 canisters/yr) in all scenarios (Fig. 12). However, data points appear to be grouped at either high or low values instead of the mean, indicating that waste arrives mostly above or below the thermal emplacement limit. Due to the bi-modal nature of the distribution (especially under the OFF and YFF5 scenarios), the mean and median may be deceptive summary statistics. A better indicator for expected demand on the CRCF might be the peak of the greater mode. The greater values are clustered near 200 TADs/yr for most scenarios, which is close to the receipt rate assumed for this study. If the receipt rate was increased to 360 TADs/yr, DOE's capacity may not sufficiently accommodate the expected demand around the greater mode. It is conceivable that the steady-state receipt rate of 3,000 MTHM could be equivalent to as many as 330-390 TADs since PWR and BWR TADs are around 8.9 MTHM or 7.7 MTHM, respectively.<sup>19</sup>

---

<sup>19</sup> This study assumed a rate of 250 TADs/year in order to send 7,500 TADs (an estimate of the total number of TADs that will be emplaced in YM) over the course of 30 years.

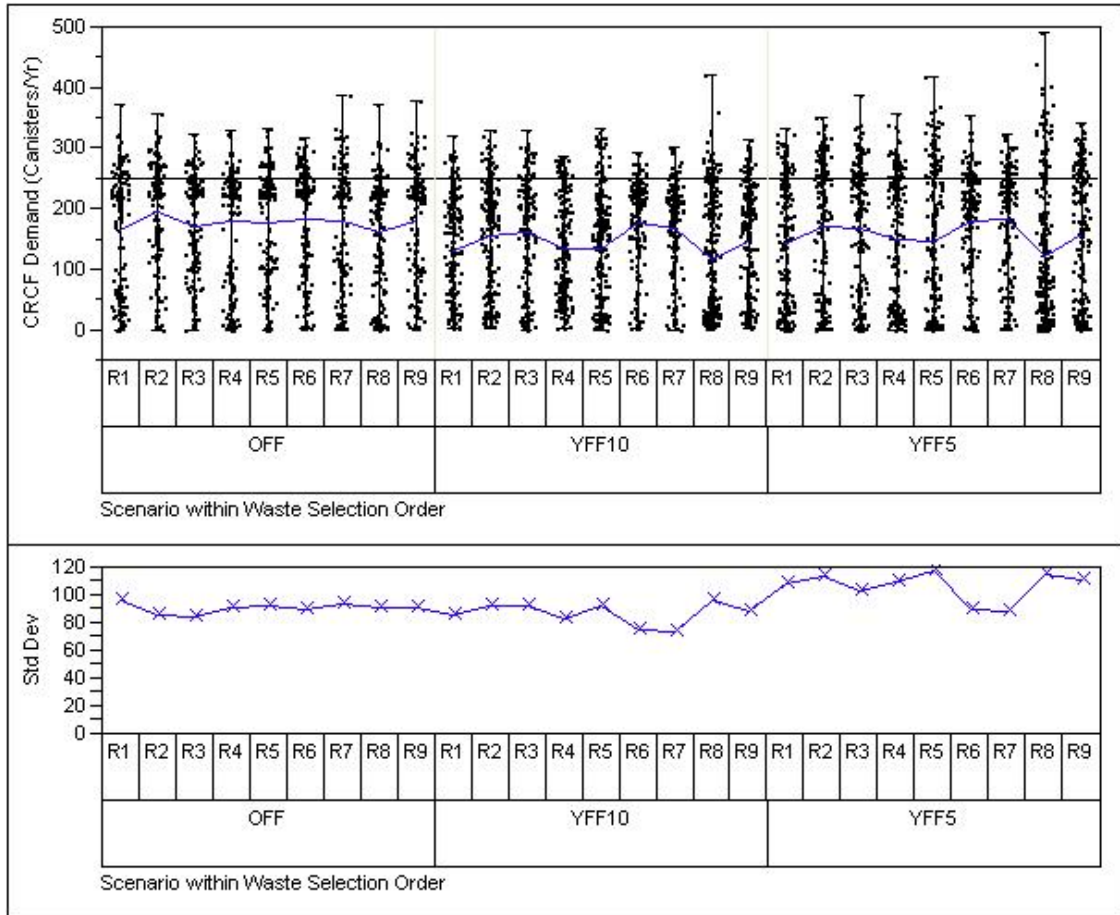

Fig. 12. Annual demand and standard deviation in annual demand for the CRCF grouped by scenario subset and waste selection order. (Scenario means are connected and a reference line at 250 canisters/yr indicating DOE's design capacity is also shown.)

The lower portion of Fig. 12 indicates that variability in demand at the CRCF is not related to waste selection order. Waste selection order does not have a clear impact on demand at the CRCF because waste that arrives too hot will eventually be routed through the CRCF to be prepared for emplacement. Under the YFF strategies, the increase in variability due to enforcing a strict thermal emplacement limit of 11.8 kW is seen in the change from R7 to R8.

### ***Receipt and Aging Facility***

Average annual demand at the RF is less than DOE's criteria of 130 canisters/yr in the OFF and YFF10 scenarios for both summaries of the resulting data (Fig. 13). Under the YFF5 scenarios, the average demand over the years in which the RF is utilized is *greater* than planned capacity in every scenario except for a low transportation limit (R6) or a high thermal emplacement limit (R7). The average demand over years including those in which the RF is not utilized is *less than* capacity in all scenarios (not shown in Fig. 13). This discrepancy is because waste is not routed to the RF after shipping is complete. In this sense, the RF sits idle during the last 20 years of the 50 year emplacement period.

Unlike the CRCF, demand at the RF is highly influenced by the order in which waste is received. The standard deviation chart of the RF shows a sharp increase in variability from R7 to R8 when a strict thermal emplacement limit of 11.8 kW is enforced under the OFF and YFF10 strategies. This is because almost the entire waste stream is routed directly to the CRCF in these scenarios.

Fig. 13. Annual demand and standard deviation in annual demand for the RF grouped by scenario subset and waste selection order. (Scenario means are connected and a reference line at 130 canisters indicating DOE's design capacity is also shown.)

Fig. 14. Annual demand and standard deviation in annual demand for the Aging Facility grouped by scenario subset and waste selection order. (Scenario means are connected and a reference line at 2,500 canisters indicating DOE's design capacity is also shown.)

The number of packages in the Aging Facility in any given year follows a similar pattern to demand at the RF. As seen in Fig. 14, the *peak* capacity is below DOE's planned 2,500 spaces in every scenario except the one that assumes YFF5 and an 11.8 kW thermal emplacement limit.

### ***Wet Handling Facility***

For the WHF, results show that DOE's throughput criteria for DPCs may not be sufficient for the volume of DPCs expected (Fig. 15). Demand for processing *bare-fuel transportation casks* is less than design criteria capacity in most years (Fig. 16). However, due to lack of available data, the DPCs and bare-fuel dry storage casks that were loaded prior to 2002 (approximately 4,200 MTHM) are not included. Therefore, the WHF may be more overwhelmed than results indicate.

The largest impact on variability in annual demand at the WHF is due to the timing of TAD availability (R1-R2). If the TAD is delayed (R1), more DPCs are included in the waste stream, increasing mean demand and variability. The R1 scenarios consider that 20%-30% of the waste stream could arrive either in DPCs or bare-fuel transportation casks. This is compared to DOE's presumed 10% limitation.

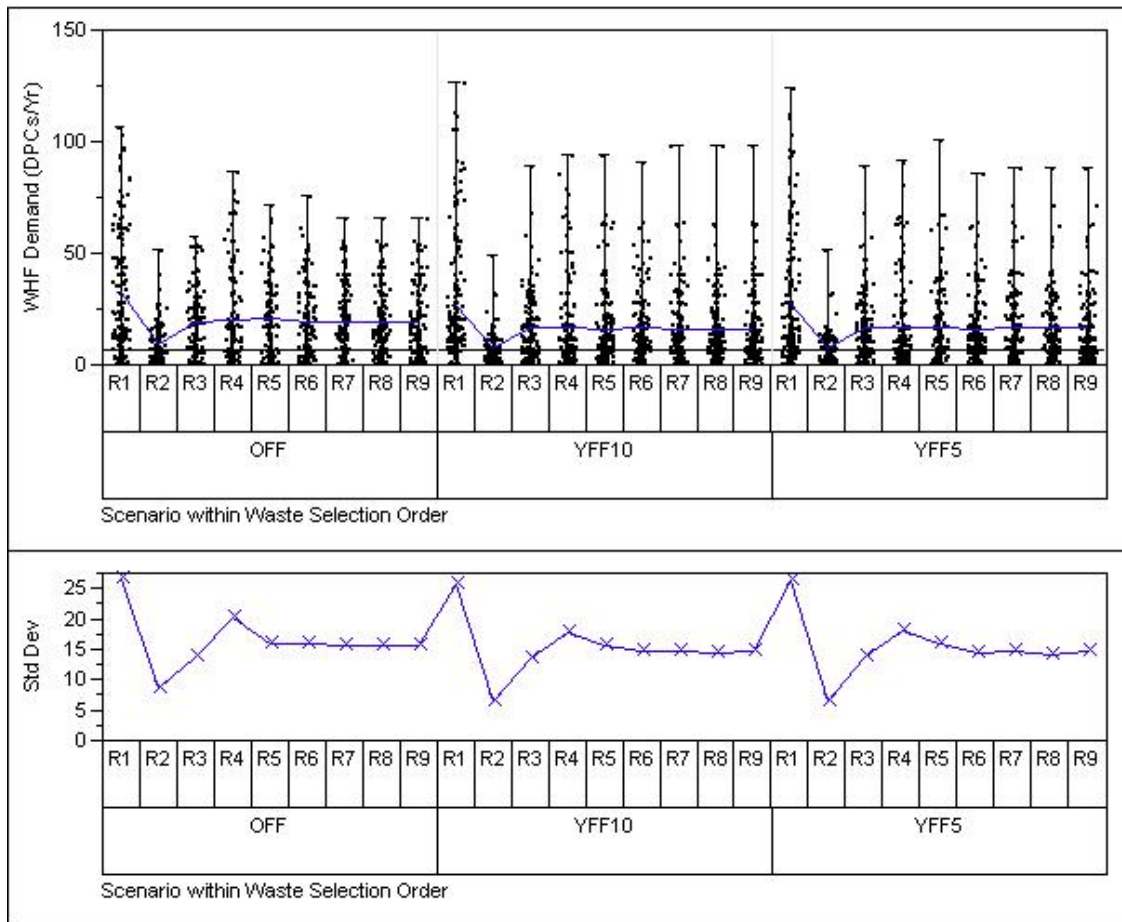

Fig. 15. Annual demand and standard deviation in annual demand for DPCs in the WHF grouped by scenario subset and waste selection order. (Scenario means are connected and a reference line at 7 DPCs indicating DOE's design capacity is also shown.)

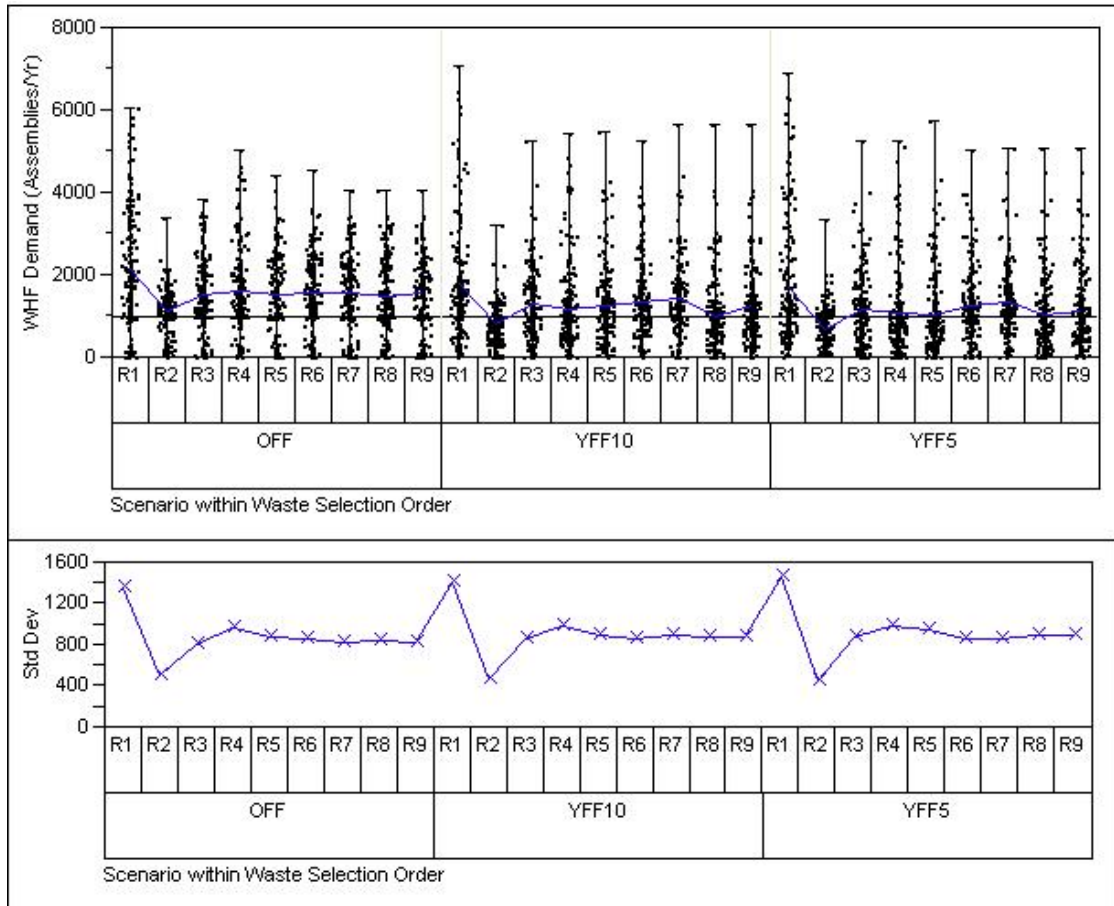

Fig. 16. Annual demand and standard deviation in demand for handling bare-fuel assemblies in the WHF grouped by scenario subset and according to waste selection order. (Scenario means are connected and a reference line at 1,000 assemblies indicating DOE's design capacity is also shown.)

### *Surface Facility Availability*

To provide a summary of the percentage of time each facility might be overburdened under the various scenarios, the number of years in which each facility was over DOE's capacity is tracked. This number is divided by the operating lifetime of the repository – 30 years for the RF and 50 years for the CRCF and WHF. The results, shown in Fig. 17, indicate that demand on WHF is above capacity in over one-half of its operational lifetime for many of the scenarios. This summary, as well as the variability charts in

Fig. 12 - Fig. 16, provide a useful broad perspective for evaluating DOE's design criteria, but they do not address particular assumptions made by DOE. Thus, a closer look at the results follows.

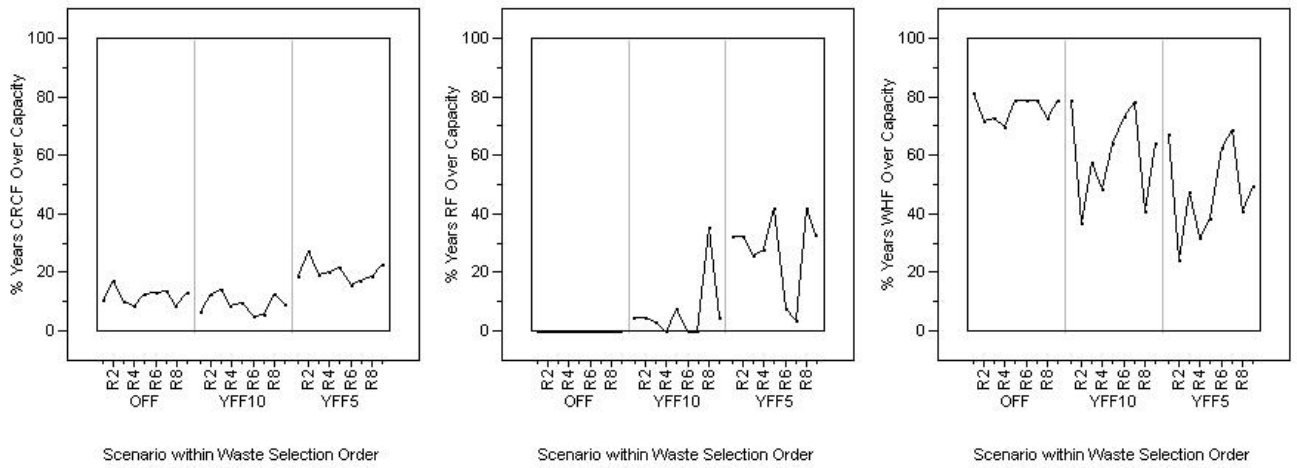

Fig. 17. Percentage of time facility is over capacity for the CRCF, RF, and WHF (from right to left). The CRCF and WHF are assumed to operate for entire 50-year emplacement period while the RF is assumed to operate for only the first 30 years.

### *Evaluation of Major Assumptions*

As described, a major assumption made by DOE in developing the throughput design is that 50% of the waste will arrive hotter than the thermal emplacement limit of 11.8 kW each year. Analysis results indicate this assumption may not be accurate depending on the order in which waste is sent to YM (Fig. 18). If oldest fuel is sent first, the average proportion is only about 10% over the entire operational period, whereas in the younger fuel first scenarios, the average ratio is about 75% for the first half of the shipping campaign, and about 40% for the latter half. Since the CRCF receives all cold TADs, and the RF receives all hot TADS, the percent of hot waste dictates demand on the RF. An inverse relationship between demands at the two facilities is apparent for the first portion of the shipping campaign (Fig. 19). Later in the emplacement period, the relationship is not as clear because the CRCF is receiving TADs that are cool enough to be taken off of the Aging Facility, in addition to newly arriving cool TADs.

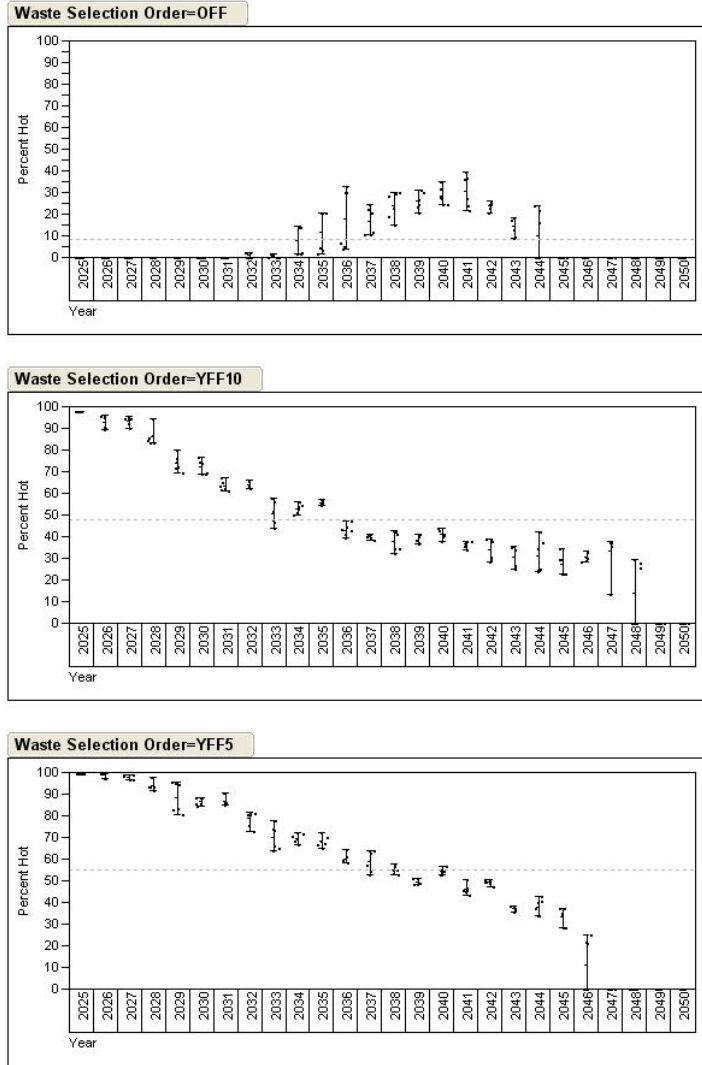

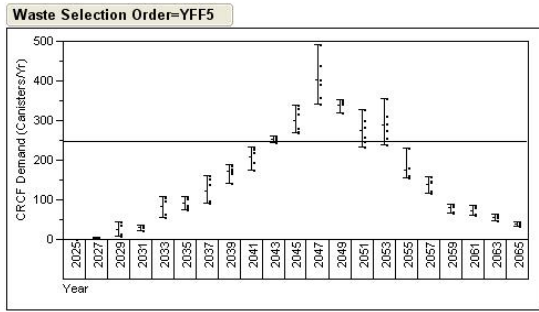

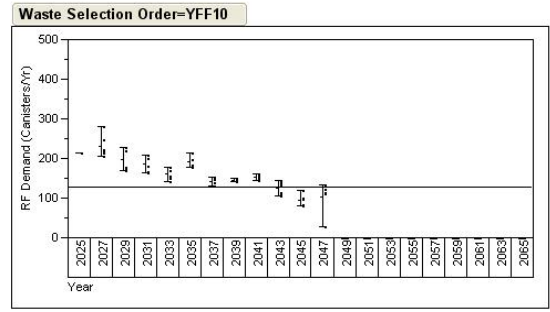

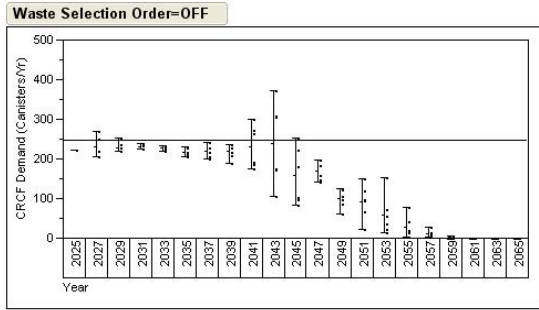

Fig. 18. Percentage of TADs above the thermal emplacement limit of 11.8 kW (out of those that are either newly arriving or cool enough to be removed from the Aging Facility each year) according to waste selection order.

The maximum demand exceeds DOE's combined capacity (250 canisters/year) even when a strict thermal emplacement limit of 11.8 kW is enforced. Interestingly, a capacity of 350 canisters/year would be adequate for 90% of the years assuming YFF5, and at least 97% assuming YFF10 or OFF. Intuitively, one might expect that sending younger fuel would reduce demand on the CRCF since more of the waste would require aging. However, results show that the peak demand is merely delayed and not reduced. This implies that there is an appropriate capacity for the CRCF, regardless of waste selection order. This inference is useful since the final schedules for delivery of waste are still undecided. It is reasonable that a CRCF built with a capacity sufficient for maximum demand could entirely replace the RF in years when the CRCF has a small demand, since RF demand would not exceed the extra capacity in the CRCF. As demonstrated in Fig. 20, the sum of demand on the CRCF and RF is below combined capacity of the facilities (380 canisters/yr) in most years.

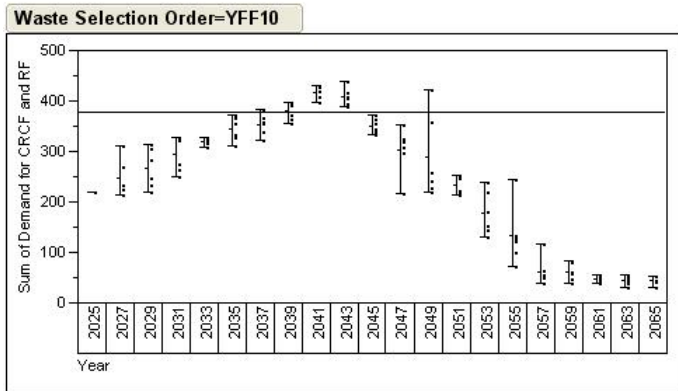

Fig. 20. Sum of demand for the CRCF and the RF assuming a thermal emplacement limit of 11.8 kW. A reference line indicates the sum of the capacity for both facilities (380 canisters/yr).

## Conclusions and Recommendations

This analysis reviewed the evolution of criteria for surface facility throughput of the TAD-based repository design. The original DOE design ignored the ratio of hot to cold canisters arriving, and thus resulted in an overly excessive design capacity. DOE developed a new design with less excess capacity. However, the following disadvantages of the design were observed:

- The design is based on an outdated waste stream study that assumed a single order for waste selection (YFF10).
- In the new design criteria, DOE assumes a 50/50 hot/cold ratio, then conservatively decides to route 70% of the 2,700 MTHM of TADs to three CRCFs instead of 50%.
- The design presumes that there will be three CRCFs without proving the need for three CRCFs.
- It includes an arbitrary 10% buffer, without showing the impact on performance, in assuming 70% of the hot TADs are sent to the RF, while 30% of the hot TADs, plus a 10% buffer, are sent to the CRCF.
- It requires the CRCF and the RF, in addition to the WHF, to handle DPCs.
- It does not account for the opportunity to couple transfer capability of the RF with welding capability of the CRCFs after all the waste has been received.

Results indicate that, under most scenarios, DOE's design adequately accommodates the *mean* demand for the CRCF and RF over the operating lifetime of these facilities. Still, due to the high potential for variability, the CRCF and RF may be used to supplement each other's capacities in the event of bottlenecks. The overlap of functional

capability confuses design goals for the system. Intuitively, a simpler design could be formulated without relying on the OWS, or expecting facilities to carry out functions for which they were not originally intended.

First, DOE could assume that, in a given year, the entire 3,000 MTHM might be CSNF. This is reasonable because CSNF constitutes 90% of the waste stream. Since DOE has stated that 90% of the waste will arrive in TADs, the 10% (300 MTHM) not in TADs should be appropriated to the WHF. Conservatively, the WHF could be designed to accommodate whichever is more demanding: 300 MTHM in bare-fuel truck casks or 300 MTHM in DPCs. Bare-fuel truck casks are smaller, but DPCs must be cut open, so it is not clear which of these is more time consuming.

This proposed design capacity for the WHF should presuppose that agreements will be negotiated between the waste generators and DOE to limit the number of DPCs and bare-fuel casks sent to YM. Before that mutual understanding is in place, it is difficult to develop an *efficient* design for the surface facilities. Accurately predicting demand for DPC processing at the WHF before the contracts are settled is problematic due to the myriad of DPC sizes in use, and uncertainty regarding which, if any, DPCs will be repackaged at utility sites. Pending future negotiations, capacity of the WHF may need to be increased in order to process assemblies that arrive in DPCs or bare-fuel transportation casks.

If information is obtained that implies it will not be reasonable to accomplish a 90% TAD waste stream, the capacity for the WHF may need to be revised. This research has provided a possible range in demand for the WHF that could be used as a starting place for determining an increased capacity. Fig. 16 shows the average annual demand for the

WHF is around 1,500 assemblies in most scenarios, with a standard deviation of approximately 800 assemblies. Assuming about half the assemblies could be PWR and the other half are BWR, 1,500 assemblies is roughly equivalent to 500 MTHM/year. This is a 60% increase above the planned capacity of 300 MTHM/year.

A design could be proposed based on this likely range of assembly demand for the WHF. However, the accuracy of this demand is limited in the underlying assumptions regarding the availability of the TAD and the adoption of its use by the utilities. In reality, the licensing and commercial development of the TAD could be delayed further than assumed, or the utilities could not adopt its use simultaneously. Thus, for the design to be robust, agreements that encourage the use of the TAD and limit the use of DPCs should still be pursued.

There is little reason to move DPCs in order to store them *again* at YM unless a waste generator is motivated to prioritize removal of DPCs over other waste from its site. Considering that DPCs are already on the aging pads at generation sites, it would facilitate YM operations if these were left at the utility site until the WHF has adequate availability. DOE should strive to negotiate schedules that uniformly distribute the shipments of DPCs over the emplacement period and avoid shipments of very hot DPCs, so the WHF might be able to handle *all* incoming DPCs and bare-fuel casks.

Instead of forcing CRCF-1 to accommodate all the waste over Years 2-4 of the ramp-up period as was done in the initial design, or assuming a 50/50 split in hot or cold packages as was done in the new design, DOE could re-frame the goals for the facilities in a way that addresses *functional* needs of the system. Since the CRCF and the RF both have the capability to transfer canisters from one type of overpack (transportation or

aging) to another (aging or disposal), the design goals could be defined in terms of *function* instead of *buildings*. In other words, the transfer design goals of the CRCF facilities could be established independently from the welding capacity design goals. This proposal does not require that the transfer and welding activities of the CRCF be housed in separate buildings. It does require TADs in disposal overpacks to be moved from the RF to the CRCF for welding with relative ease. This is considered a reasonable requirement since the SEIS already allows for this type of movement.

The transfer capability could be guided by the receipt-rate ramp-up period during the first five years, but it should be at least 3,000 MTHM per year during steady-state operations. Minimum welding criteria should match the best-case scenario for emplacement constrained only by thermal limitations. In other words, surface facilities should be capable of welding and emplacing the total 3,000 MTHM each year. If excavation of the drifts cannot possibly accommodate 3,000 MTHM per year, then it is recommended that the receipt-rate be re-evaluated. It is reasonable to expect that almost all the packages arriving will be TADs that are less than the thermal emplacement limit in some years, and thus will be ready to be welded. If welding does not meet the demand for disposal packages thermally ready to be welded in a given year, the design could result in *unnecessary* above-ground aging or storage of the waste.

The welding capability could be built in stages over the ramp-up period, depending on the drift excavation plan and the negotiated schedules that will be set in the future. The first 1,000 MTHM of welding capability could be built in CRCF-1, possibly in increments of 500 MTHM over two years.

The RF could be used for transferring canisters to aging overpacks during Years 2-3. In Year 4, when CRCF-2 is meant to come on-line, the RF could carry out the transferring capability for CRCF-2 by placing canisters into disposal overpacks. Instead of building an entirely new CRCF with transfer *and* welding functions, only additional welding capability would be necessary. The 3<sup>rd</sup> CRCF could be built with both transfer and welding capacity, or more welding capacity alone if that would be sufficient.

A system where CRCF welding capacity is equal to, or greater than, the transfer capacity should be considered for two reasons. First, TADs ready to come off of the Aging Facility and those newly loaded in the WHF – in addition to the newly arriving TADs - will need to be welded at the CRCF. Ideally, the TADs loaded in the WHF could be placed directly in disposal overpacks and welded instead of being aged first. Second, under the current design, there is no need for the RF to receive waste after shipping is complete. Considering that transfers will need to take place after all the waste has arrived, the RF capacity should be utilized for transferring canisters to disposal overpacks in later phases of the operation. In other words, the CRCF should not be expected to carry out all transfers while the RF sits idle.

The proposed alternative criteria are summarized in Table 20. Transfer capability is greater than the receipt rate in each year of the ramp-up phase. Welding capacity is equal to the amount received in the steady-state rate, and it is just under the receipt rate during the ramp-up years. The proposed design has an increased welding capability over DOE's design, but a decreased transfer capability. This is achieved by eliminating the need for the transfer segment of CRCF-2. The design would allow for a steady flow of

emplacement while implementing a uniform approach for incrementally added construction.

The goals presented are not based on a specific waste stream study, or an assumption that any particular ratio of waste will arrive above or below the thermal emplacement limit. The steady-state capacity calls for a total of 360 TAD equivalents per year as compared with DOE's 460 canisters/year. Because the design goals do not provide excess capacity over the steady-state receipt rate, they should be considered as a starting place for defining the final criteria. The ability to meet performance criteria should incorporate a margin of error for facility availability, using what is considered appropriate given factors such as the reliability rate of the equipment.

Table 20

| TAD<br>Welding               | 500    | 60   | 1,000  | 120  | 1,000  | 120  | 1,500  | 180  | 3,000    | 360  |

CRCF-1 and 3 have transfer and welding capabilities, RF has transfer capabilities, and CRCF-2 has welding capabilities only.

Future studies should revisit data regarding dry storage at the waste generation sites. Inventories of dry storage loaded prior to 2002 that were omitted in this analysis should be investigated to determine the number of DPCs included in this portion of the waste stream and how this might impact demand on the WHF. Variations in the proportion of non-DPC waste arriving as bare-fuel (assumed to be 12% in this study) and the maximum receipt-rate (assumed to be the equivalent of 250 TAD/yr) should be evaluated. Additional waste streams could be developed by treating the minimum age of fuel that is selected in the youngest fuel first scenarios as a random variable (e.g., YFF6-YFF20). The more waste streams that are considered, the better understanding DOE will achieve of uncertainty regarding the likely throughput demands of the facilities.

Future enhancements to the model could support throughput analysis by limiting the number of packages that can be processed each year, including a phased increase for the CRCF capacity. DOE's current design criteria could be measured against the design proposed herein under the various pre-closure scenarios. This will help to predict the timing of the need for the second and third CRCF, as well as define goals for progress on drift excavation.

## **CHAPTER V**

### **SUMMARY**

This research aimed to measure the impact on ‘operational performance’ of multiple scenarios for management of CSNF at Yucca Mountain, NV during the pre-closure emplacement period. The term operational performance, not to be misinterpreted as the “pre-closure performance objectives” defined in 10 CFR § 63.111, is specific to this dissertation. Desired operational performance of the waste management system includes: (1) reducing dry storage requirements at the utility reactor sites, improving the efficiency of the transportation movements, (1) reducing the number of shipment origin locations per year, (3) meeting the receipt-rate goals for YM, and (4) reducing the number of material handlings at the surface facilities.

Research objectives were accomplished by framing the pre-closure emplacement phase of YM operations as an integrated system that includes the waste generation sites and the various surface facilities at YM. A flexible simulation tool was developed for evaluating the relative operational performance of different pre-closure scenarios. Through application of the tool, a better understanding was gained of how thermal characteristics of the CSNF, upon arriving at YM, are dependent on the design assumptions of the system. Design assumptions include: (1) utility behavior regarding dry storage loading, (2) thermal limits for transportation and emplacement, (3) TAD availability, and (4) repository timeline for opening and receipt of shipments. Advantages and disadvantages of certain operating strategies were identified in terms of

multiple performance metrics, notably safety considerations and throughput of surface facilities. This led to an opportunity for recommending scenarios that have potential to result in improved operational performance.

## **Conclusions**

The major conclusions stemming from this research are as follows:

- Allowing Purchasers to trade allocations, prioritizing the trades based on least remaining capacity in the reactor-site spent nuclear fuel pools, reduces the dry storage demands at the utility sites and the average number of pools making shipments in a given year, while increasing the efficiency of transportation (Chapter 2).
- Due to the large number of utilities that will need to increase their dry storage capacity between now and the likely opening of the repository, near-term availability of the TAD is important for reducing the number of DPCs that will potentially be sent to YM for repackaging into TADs. (Chapter 2).
- If younger fuel is sent first and the legal limit of YM remains 70,000 MTHM, above-ground aging demands at YM can be reduced by reducing the thermal transportation limit for the TAD. This is feasible because DOE, as opposed to the vendor, is responsible the design specifications of the TAD. (Chapter 2).
- Relaxing the thermal emplacement limit, if proven to be compatible with the overall thermal management strategy for the repository post-closure, is the most effective way to reduce above-ground aging requirements at YM (Chapter 2).

- Scenarios that required fewer canisters to be aged and scenarios that contained fewer DPCs resulted in lower frequencies of a drop event. DOE should consider negotiating agreements that limit the number of canisters that need to be aged at YM, as well as encourage early adoption of the TAD (Chapter 3).
- Due to the uncertainty surrounding future waste schedules, DOE should consider adopting a probabilistic approach to estimating the frequencies of events in its pre-closure hazards analysis (Chapter 3).
- Pending future agreements between waste generators and DOE, capacity of the Wet Handling Facility may need to be increased in order to efficiently handle assemblies arriving in DPCs and bare-fuel transportation casks (Chapter 4).
- Because design goals for throughput have been defined in terms of surface buildings as opposed to functional needs, there is a redundancy in functional capability of the CRCF and the RF which should be taken into account in order to design a more efficient system. A design based on functional demands of the system would be easier to evaluate in terms of its ability meet performance objectives (Chapter 4).

Pre-closure operational performance of the waste management system of YM depends on the decisions of multiple stakeholders. The commercial utilities, cask vendors, DOE, NRC, and the public (to name a few examples) are all actors with different roles, responsibilities, and risks to manage. Furthermore, the impacts of pre-closure actions and decisions are time-dependent. The timing of events such as commercial development of the TAD, opening of the repository, or availability of a

separate interim storage facility all introduce considerable uncertainty into the potential waste stream for YM.

An important lesson from this research is that less complicated aspects of a system can still considerably impact overall performance. One cannot take for granted that a particular component of a project will be easy to implement just because it is less complex or has been carried out successfully in the past. The fact that less emphasis was placed on pre-closure operations relative to post-closure performance resulted in a disconnection between pre- and post-closure analyses. If pre-closure utility selection for loading assemblies had been thought of as having more potential to impact the amount of aging required above ground at YM, a more appropriate agreement might have been reached when the *Standard Contract* was developed.

Also, it is noted that for these types of projects, proving compliance through application of conservative, deterministic assumptions may not reveal the potential efficiencies that can be gained through parameter trade-offs. In some cases, deterministic, conservative approaches may not have the desired result if the basis for the conservative assumption is not explained. An example lies in the safety and throughput analyses conducted by DOE. These studies made conservative assumptions, but without a contextual understanding of how the assumptions impact the overall ability to achieve design objectives. This type of approach can limit the ability to effectively communicate the uncertainty surrounding the performance of the system. In these cases, a probabilistic approach that does not rely as heavily on conservative assumptions may help strengthen risk communication.

## Recommendations For Future Research

As in any comprehensive research endeavor, opportunities for further enhancement abound. In this instance, the following activities are recommended for continuing research progress:

- Incorporate a complete inventory of assemblies already loaded in DPCs and SPCs into the database to gain a more comprehensive knowledge of the current status. To better predict potential *future* inventories, a survey could be conducted that asks waste generators about their willingness to use the TAD. On-going studies evaluating the ability to directly dispose of DPCs should also be considered.
- Develop an economic response variable that considers both the utility and YM expenses relating to storage. Utility costs include those associated with storing TAD canisters that are potentially more expensive than current dry storage systems and have a smaller capacity, meaning the utilities would have to store a greater number of them to accommodate the same number of assemblies. Meanwhile, expenses at YM will be related to the size of the Aging Facility and the duration of operations for the surface facilities, which is largely driven by the length of time the casks need to be aged above ground.
- Construct additional scenarios using a Latin Hypercube Sampling (LHS) method for the continuous parameters to gain a better understanding of parameter relationships. In addition to the four continuous parameters used in this study, future studies could define the percent of waste arriving in bare-

fuel transportation casks, the steady-state receipt rate, and the minimum age in the youngest fuel first scenarios as random variables.

- Focus the simulation on the five year ramp-up phase, incorporating a shorter time-step, to better determine the appropriate timing for increased capability in the CRCF and to better predict the main drivers for processing delays. The proposed facility capacity constraints could be tested under various scenarios, and delays in the system could be measured.
- Include geographical information as an additional feature for the facilities so that additional metrics involving transportation (e.g., travel time) can be tracked. This would aid in identifying scenarios that take advantage of the ability to collect shipments from multiple facilities on a single dedicated train.
- Utilize the model's capability to dynamically create a waste acceptance schedule for additional objectives (e.g., prioritize allocations to sites in certain geographical regions, sites with specific transportation capabilities, or sites with a specific inventory of loaded TADs/DPC, etc.)
- Finally, explore the potential to frame the research as an optimization problem. To do this, one would have to decide the appropriate design parameters, constraints, and candidate objective functions. For example, one could find the CRCF throughput capacity that minimizes the average of maximum demands on the Aging Facility, constrained by a minimum limit on excess capacity in the CRCF. Or, the model could be used to identify the optimal thermal emplacement limit between the values of 11.8 kW and 18 kW

that keeps the capacity on the Aging Facility at or below 2,500 dry storage containers, given a particular receipt rate and waste stream.

These continued research efforts will help provide a more comprehensive understanding of likely waste streams for YM, and in doing so, enable the design of a more efficient pre-closure waste management system.

## APPENDIX A

### DETAILED MODEL DESCRIPTION

#### Model Scope and Objective

The modeling tool developed for this analysis is used to gain a better understanding of repository surface operations. The simulations are carried out from the present time and through the *emplacement phase* of the pre-closure period. The objective is to estimate the thermal power output of packages as they are loaded at the utilities and sent to YM. The model does not calculate temperatures associated with the subsurface of the repository (e.g., midpillar, cladding, waste package, and drift wall), which is considered outside the scope of this analysis.

#### Data

##### *Commercial Spent Nuclear Fuel Inventory*

Raw data is taken from RW-859 database provided by the Energy Information Administration. RW-859 is an MSAccess Database that provides data on irradiated fuel assemblies. The table called tblFuelFresh includes assembly characteristics (burnup, initial loading weight, enrichment, discharge date) for all discharged assemblies. This table also indicates if the assembly was in dry storage or not, but does not indicate which assemblies were in each particular dry storage cask at a specific reactor site. In order to

isolate the spent nuclear fuel assemblies that were still in the pools from those that were not, a new table, called tblFuelFreshWet was created, without the dry storage assemblies loaded into dry storage prior to 2002. Because data regarding how the assemblies in dry storage were loaded into different dry storage containers was not available, the assemblies in dry storage prior to 2002 were not included in the data set.

Projected assembly discharges were calculated using a Microsoft Excel macro created by Department of Energy and documented as an appendix to *Calculation Method for Projection of Future Spent Nuclear Fuel Discharges*.<sup>1</sup> The macro, “FINAL\_UTIL\_SNF\_PROJ\_1998.xls”, projects future fuel discharges based on site closure times, and assumptions regarding trends in burnup and enrichment values.

A table, such as the following, summarizing the discharge cycles 1 to n is created using MSAccess for each pool.

| Cycle | Date discharged | Avg Burnup (GWd/MTU) | Avg Enrichment | Avg Mass per Assembly (kg) | Starting Assembly Count |
|-------|-----------------|----------------------|----------------|----------------------------|-------------------------|
| 1     | 1/1/1979        | 12                   | 3%             | 460                        | 46                      |
| n     | 1/1/2015        | 50                   | 5%             | 425                        | 157                     |

The summary tables for each pool are uploaded into the GoldSim as separate arrays for each column. These elements, along with the capacity of the spent nuclear fuel and the fuel type (PWR or BWR), are held within the “Unique” container for each pool. The capacity used is the licensed capacity provided in the RW-859, which does not include a full core reserve. The capacities could easily be redefined by the user to reflect

---

<sup>1</sup> “Calculation Method for Projection of Future Spent Nuclear Fuel Discharges.” TDR-WAT-NU-000002

a full core reserve. Each year, the GoldSim submodel Heat\_Table is updated to change the average thermal output of each assembly within a discharge cycle, and the remaining assembly count is updated for each discharge cycle for each pool. Negative ages are used to represent future discharge projections.

Variable names as they appear in the code are provided in parentheses. The burnup (Btot), and enrichment (Enrichment) were averaged over the number of assemblies discharged at each historical and projected discharge date (Download\_Date). The discharge date must be imported into GoldSim in the serial value format, so it is converted to a date (Date\_in\_pool). The model calculates the number of years the assembly has cooled out of the reactor (Tc) based on the current year of the model. A submodel is created for each pool that calculates the thermal power each year, called Heat\_Table. FuelTypeID describes if the pool is PWR (0) or BWR (1).

The model uses a different set of lookup tables for PWR and BWR fuel type that contain thermal power estimates for various time cooled, burnup, and enrichment values. Thermal values are interpolated logarithmically between time cooled and linearly between enrichment and burnup values using the GoldSim element "Lookuptable". Data uploaded to the Lookuptable was obtained from Bruce Kirstin, a staff member of the Nuclear Waste Technical Review Board. The data is the same that is used by DOE in a previous study (BSAIC 1999). The thermal decay heat for each cycle discharge cycle is stored in the array Current Heats.

## Utility Dry Storage Loading Before YM Opens

The “Clone” portion of each pool holds the logic for loading dry storage. The variables for each pool have the same logic structure, but different values since they are linked to data elements in the “Unique” container belonging to that pool. Each pool has two arrays assigned to it that are of an adequate length to be able to represent all the dry storage containers that pool would load over its entire lifetime. Every cell in each of the array represents one container.

One array is used to track the heats of the containers that have been loaded (Container\_Heats) and the second array tracks the container type and location (Container\_Location), stored as an integer 1-6 in each cell of the array. The integer represents a combination of container type and location. The container type can either be a DPC or a TAD, and the container location can be at YM or at the utility site. Dry storage containers that were once on the dry storage pad of the utility but have been shipped to YM are stored as a separate integer than dry storage containers that were shipped directly after being loaded from the pool.

The integer assignments for Container Location are:

- 1 if TAD at YM
- 2 if DPC at YM
- 3 if TAD at reactor
- 4 if DPC at reactor
- 5 if at reactor and loaded after YM has reached capacity
- 6 if TAD was once at reactor site and has been moved to YM

Each year, the model checks to see if assemblies should be loaded into dry storage from the pool. Assemblies are loaded if the pool has reached its capacity, or if a shipment to YM is scheduled. If the TAD is available (checked by comparing the

simulation year to the user input variable TAD Year), then the canister is marked as a TAD, if the TAD is not yet available, then the canister is marked as a DPC. The model refers to the fuel type to check for the number of assemblies that should be in the canister. All PWR canisters have 21 assemblies and all BWR canisters have 44 assemblies.

The assemblies in DPCs are originally grouped into 21 and 44 sized sets so that the same logic could be used for loading TADs and DPCs. This was also a useful assumption for determining when the correct number of TAD equivalents would be loaded, triggering that it had reached YM Capacity. The number of DPCs arriving at the surface facilities was adjusted for the difference in size of the DPCs as a part of post-simulation data processing.

The logic for choosing assemblies to load in containers is housed within the “Loading” container in each pool. One of three orders for selecting spent fuel assemblies from a facility’s pool is applied: (1) oldest fuel first (OFF), (2) youngest fuel first at least five years old (YFF5), or (3) youngest fuel first at least ten years old (YFF10).

The loading algorithm can accommodate zone loading or uniform loading, set by the user. For each zone of a dry cask, the minimum cooling time requirement per assembly will be assumed. The heat limit per assembly (Goal) is defined as the hot value for the first 9 or 20 assemblies, depending on the fuel type. The cold value is used for the remaining assemblies. The value is calculated using the transportation heat limit defined by the user.

In the case that not enough assemblies meet the criteria to fill the cask, the utility will wait to load the cask until it has the appropriate number of assemblies that meet the criteria.

The logic for the loading algorithm is as follows:

- For each cask
  - Is this cask a PWR or BWR cask?
    - Set appropriate sizes for zones and decay heat limit per assembly
- For each zone in the dry cask, starting with the cold zone, then going to the hot zone
  - If YFF5 or YFF10: Look for youngest assembly that meets per assembly decay heat requirement
  - Else, OFF: Look for oldest assembly that meets the per assembly decay heat requirement
  - Load assembly
  - If pool is empty, close cask (to ensure last cask is closed even if it is short loaded)
  - Else repeat until zone is full or no more suitable assemblies remain
    - If zone is full or if short loading is allowed
      - End zone and move to next zone
    - Else, wait until more assemblies age and attempt to load again
- Repeat until cask is full, close cask

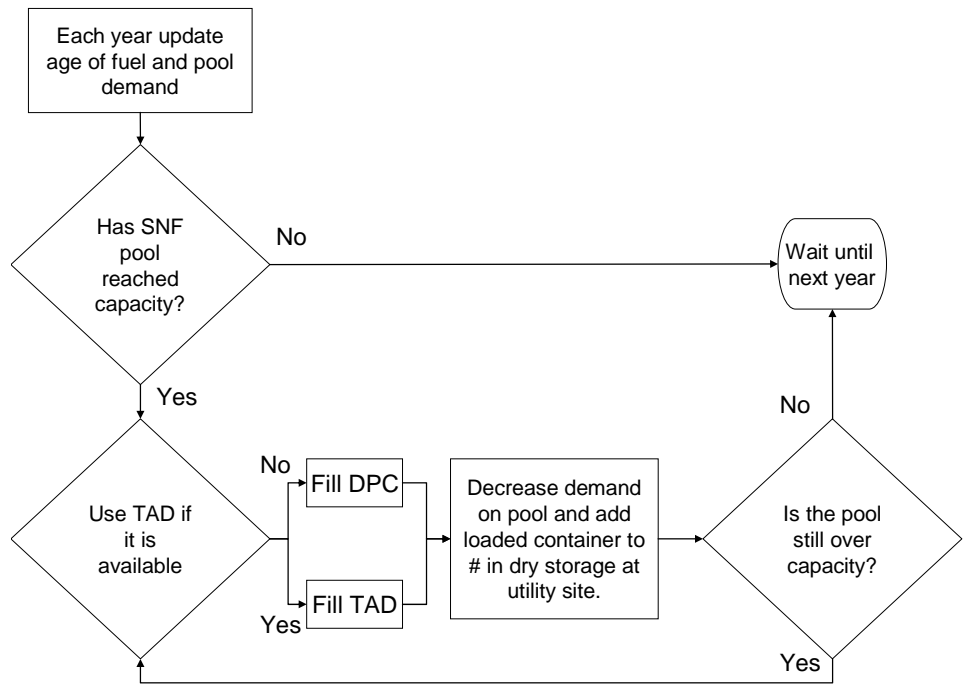

The logic for assigning assemblies to containers is held within a container (Assign Container) within each pool. Each time an assembly is loaded, a vector (Removed Condition), which is the same length as the number of discharge cycles, is updated. This vector is marked with a 1 in the cell associated with the cycle discharge group from which the assembly was removed. The vector Removed Condition is used as a row corresponding to the current container being loaded in a matrix (Assignment). The matrix is updated each time an assembly is transferred. The next row is populated once the last container is full. The Assignment matrix is used to calculate the total heat of each container by multiplying it with a vector that tracks the average heat of the assembly within each cycle discharge group.

## Assign Thermal Power Output to TADs

The logic for dry storage loading before the repository opens is summarized in the diagram below. This process continues on an annual basis until the simulation reaches the year that the repository opens, which is defined by the user.

The variable Count Load indicates how many containers should be loaded from each pool each year. Before the repository opens, this value will be the number of containers that the pool is over capacity. The count of containers is according to the fuel type of the pool, 21 for PWR and 44 for BWR, rounded up to the next full container.

### **Shipments to YM**

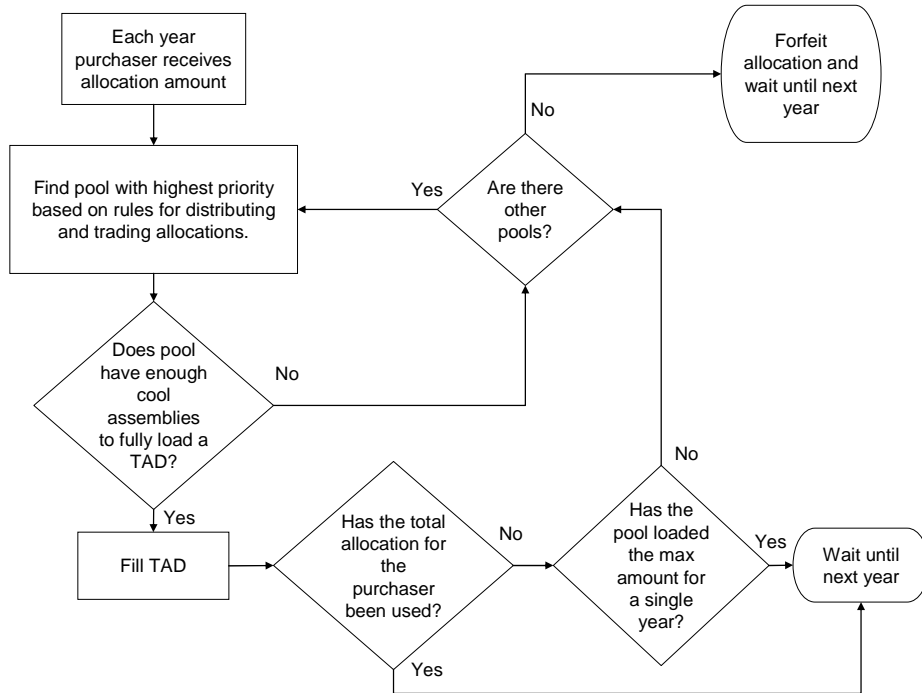

Once the repository opens, a particular number of shipments (ranging from 0- MaxSendTrain containers) to be sent to YM are assigned to each pool. Shipments to the repository are triggered by the Allocator Element within GoldSim and are modeled as discrete transactions on a yearly basis. The Allocator Element within GoldSim is utilized to create a dynamic shipment schedule, allocating shipments from waste generation facilities based on pre-defined priorities, such as the age of the fuel or the available capacity for storage in the spent nuclear fuels at the waste generation sites. Two separate strategies are implemented for allocations.

One strategy utilizes the Allocator within each operator group (Allocator1). The yearly input to this allocator is pre-determined from an MSAccess table that was created (AllocUtiliyYear) and uploaded into Golsim as separate arrays (AllocationUtility) in the CloneAllocation container of each Purchaser Group which lists the allocations in units of TADs each year for each Purchaser. It was created based on an oldest fuel first order, allocating a total of 300 TADs per year. The Allocator for each Purchaser is only linked to the pools that are owned by the Purchaser. Another strategy uses a single Allocator (AllocatorAll) for all the pools. The input for this allocator is the amount of the entire

receipt-rate for YM in a given year. Allocations continue each year until YM has reached capacity.

Priorities for the allocations can be adjusted as variables. The options include choosing the pool with the: hottest assembly (1), coldest assembly (2), or least remaining capacity (3). The demand of each pool is either the maximum number of shipments in a given year, or the number of shipments left in the pool that are cool enough to send to YM. When the total number of containers that are destined for YM have been loaded, the demand is equal to the containers that are remaining on the dry storage pad that were loaded before YM opened. This ensures that TADs that were loaded *before* YM opens are eventually sent to YM.

Allocation distribution and loading can be described with the following logic:

The variable Allocation indicates the amount that has been allocated to a pool each year. It is the minimum of the output of the Allocator Element and the maximum amount a pool can send in a given year (MaxSendTrain).

The variable CountLoad is still used to indicate the number of containers that should be loaded each year after YM opens, however now it is the allocation amount minus both the DPCs that should be sent from dry storage that year (CountSendFromISFISI) and the TADs that should be sent from dry storage that year (CountSendFromISFISI\_1). CountLoad is zero if the capacity of YM has already been reached or if the allocation is zero. If the pool needs to load because it is over capacity, it still does so, but the total amount the pool loads will be the amount it needs to in order to not be over capacity plus the remainder of the allocation after it loads that amount. This

ensures that a pool will not load more than the total allocation, unless the amount it needs to load because it is over capacity is greater than the allocation.

The CountSendFromISFISI (for TADs and DPCs) is a function of the variable that controls if the utility sends dry storage containers before loading from the pool (Pool First) and the preference for removing dry storage containers (SendOrder). If the dry storage pad is to be emptied before the pool, then it will try to fill the entire allocation with dry storage containers of choice. If TADs are sent first, and there are enough to fulfill the entire allocation, then it will send no DPCs. If DPCs are sent first and there are enough TADs left, then it will send zero DPCs. When the top priority container is gone, it will fulfill the allocation with the second priority container. If a proportional amount is to be sent, then it will send a proportional amount of the allocation, depending on how many TADs or DPCs are in storage and the size of the allocation. If the pool is the top priority indicated by PoolFirst, it will only send from the dry storage pad when there are not enough cold assemblies in the pool to fulfill the allocation. The same rules are followed for choosing a container based on SendOrder.

DPCs or TADs are removed in the order in which they were put on the dry storage pads, or first in first out. The variables (NextIndexStorage) and (NextIndexStorage\_1) track the index of the next TAD and DPC that should be taken from the dry storage pad each year.

Allocations continue until YM has reached capacity. When the total number of containers that have been loaded is equal to the limit for YM, then YMCapacity will turn to true. Since some of the containers that were loaded may not have been sent to YM yet, when YMCapacity is true, the TADs and DPCs that were loaded before YM opened and

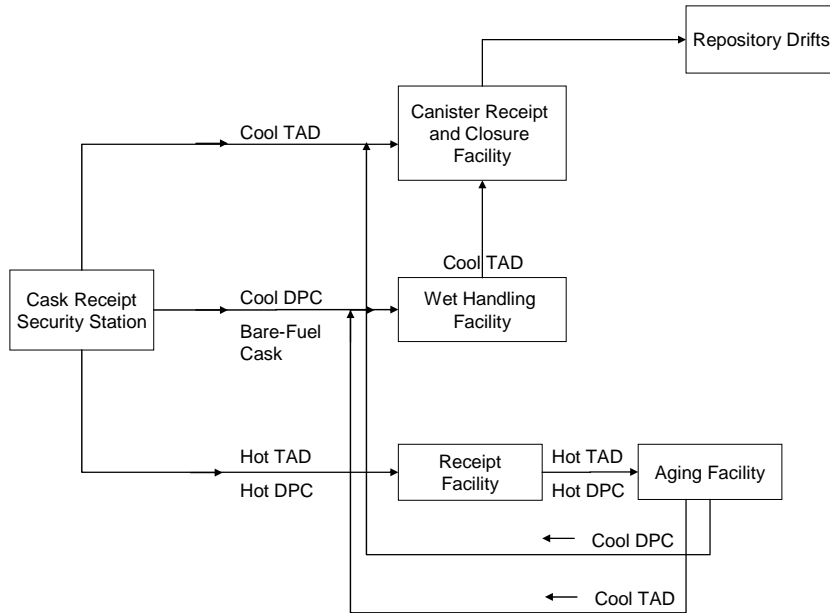

remain on the dry storage pad are sent to YM. However, the dry storage that was loaded because the pool was over capacity while YM was receiving waste will remain on the storage pad at the utility sites. These are labeled as CountAfterCap packages because they are not included in the total inventory planned for YM.

### **Surface Facility Logic**

GoldSim Elements tracking the cumulative amount of shipments that have been sent to YM and are either above or below the thermal emplacement limit are also defined. These are summations of the containers associated with the pools that are either above or below the emplacement limit and are marked as sent to YM in the Container Location Array.

Since the model categorizes containers as DPC or TAD, a percentage of the assemblies that are not in DPCs are assumed to arrive as bare-fuel casks, and are routed to the WHF each year. The demand in units of DPCs to the WHF is adjusted from a 21 PWR, 44 BWR sized canister to be equal to a 36 PWR or 74 BWR canister.

Demand on the surface facilities is determined based on the following flow model:

## User Defined Input Variables

| Variable Name                      | Variable Description  | Unit           | Level 1                        | Level 2                                     | Level 3                                       |
|------------------------------------|---|----------------|--------------------------------|---|---|
| TAD Year<br>(Kouts 2006)           | Year TAD becomes available  | Year           | 2012                           | 2016  | 2020  |
| Repository Year<br>(Williams 2006) | Year DOE starts accepting commercial spent nuclear fuel (assumed to begin with the steady-state receipt rate)                 | Year           | 2020                           | 2025  | 2030  |
| Heat Limit<br>Transportation       | The maximum thermal output allowed at time of packaging for storage at utility site   | kW             | 18kW                           | 21.5kW                                      | 25kW  |
| Loading Transport                  | Utility preference for choosing assemblies from the pool to load into dry storage   | N/A<br>(Logic) | YFF at least 5 years old       | YFF at least 10 years old                   | Oldest fuel first                             |
| Send Order                         | Utility preference for removing casks from dry storage  | N/A<br>(Logic) | TAD                            | DPC   | Proportional Amounts                          |
| Pool First                         | Utility preference for removing waste stored on-site  | N/A<br>(Logic) | Pool First                     | Dry Storage Pad First                       |   |
| Trading                            | Allocations are assigned either to specific reactor pools or to purchasers. Purchasers are also allowed to trade allocations. | N/A<br>(Logic) | Assigned to reactor pools      | Assigned to purchasers                      | Purchasers allowed to trade                   |
| Priority Method                    | Purchases may be allowed to trade allocations   | N/A<br>(Logic) | Based on youngest fuel in pool | Based on oldest fuel in pool                | Based on least remaining capacity in the pool |
| Emplacement Limit<br>(BSAIC 2005)  | The maximum thermal output allowed at time of emplacement for a WP  | kW             | 11.8 kW                        | 14.9 kW                                     | 18 kW   |
| YM Cap Number<br>(DOE 2006a)       | Assumed number of TADs to be emplaced in YM.  | Number of TADs | 7,500                          | Large enough to emplace all projected waste |   |
| Receipt-Rate for YM                | The number of TAD-equivalents sent to YM each year.   | Number of TADs | 300                            | 250   |   |
| Max Send Train                     | Maximum number of TADs that can be sent from a single facility in one year  | Number of TADs | 10                             |   |   |

## Response Variables and Data Analysis

Scenarios are carried out by housing the model within an outer model that feeds the input variables for each deterministic realization. As each scenario is carried out, response variables are recorded yearly to a Microsoft Excel workbook; each row is a year of the simulation, and each column represents a different scenario. The response variables, tracked separately for each pool, are located within the container labeled “Expose to Pool”. The variables within this container are exposed to the pool level, meaning they are linked to variables outside of the pool container. This way, the response variables are summed over all the pools to obtain a value for the entire set of pools.

| <b>Response Variable Name</b> | <b>Variable Description</b>  |
|-------------------------------|--|
| Count After Cap               | Casks that are loaded after YM reaches capacity due to lack of capacity in the spent nuclear fuel pools at the utility sites |
| Count Aging DPC               | DPCs that are at YM and above the emplacement limit  |
| Count Aging TAD               | TADs that are at YM and above the emplacement limit  |
| Count At YM                   | Total number of TAD equivalents at YM  |
| Count DPC                     | Total number of DPCs loaded  |
| Count Emplaced DPC            | Canisters marked as DPCs that are below the emplacement limit and sent to the WHF to be reloaded into TADs and emplaced      |
| Count Emplaced TAD            | TADs that are at YM and below the emplacement limit  |
| Count Empty                   | Count of the number of empty pools   |
| Count ISFSI                   | Count of TADs in dry storage at the utility sites  |
| Count Loaded                  | Total count of containers that have been loaded  |
| Count Pools                   | Number of pools sending shipments to YM in a given year  |
| Sum Pool                      | Number of assemblies in wet storage  |

## Scenarios

Scenarios were carried out in a deterministic fashion in order to gain an understanding of the relative importance of each input variable with respect to how it impacted the response variables.

A total of 81 scenarios were considered for the analysis described in Chapter 2. Nine sub-scenarios were created by manipulating four variables (year YM opens, year TAD becomes available, transportation thermal limit, and emplacement thermal limit) from their high to low values while holding all others at their central value. Each of these *nine* sub-scenarios was considered under *three* utility assembly selection loading behaviors (YFF5, YFF10, OFF), creating 27 combinations of sub-scenarios with assembly selection orders. This set of 27 scenarios was repeated 3 times: (1) assuming that purchasers did not trade allocations and a capacity of 7,500 TADs for YM, (2) assuming purchasers did not trade allocations and an expanded capacity of YM, and (3) assuming that purchasers could trade allocations based on least remaining capacity in the spent nuclear fuel pools for the current legal capacity of YM. This created a total of  $9 \times 3 \times 3$ , or 81 scenarios.

| <b>Sub Scenario Parameter Adjusted</b> | <b>Subscenario ID</b> | <b>Value</b> |         |
|--|-----------------------|--------------|---------|
| Year TAD in Use                        | R1                    | High         | 2020    |
|  | R2                    | Low          | 2012    |
| Year Repository Open                   | R3                    | High         | 2030    |
|  | R4                    | Low          | 2020    |
| Transportation Heat Limit              | R5                    | High         | 25 kW   |
|  | R6                    | Low          | 18 kW   |
| Emplacement Heat Limit                 | R7                    | High         | 18 kW   |
|  | R8                    | Low          | 11.8 kW |
| All Subscenario Parameters             | R9                    | Central      |         |

| <b>YM Capacity</b> | <b>Allocation Trading</b>      | <b>Assembly Selection</b> | <b>Subscenarios Explored</b> |
|--------------------|--------------------------------|---------------------------|------------------------------|
| 7500 TADs          | No                             | OFF                       | R1-R9                        |
|                    |                                | YFF10                     | R1-R9                        |
|                    |                                | YFF5                      | R1-R9                        |
|                    | Based on capacity in SNF pools | OFF                       | R1-R9                        |
|                    |                                | YFF10                     | R1-R9                        |
|                    |                                | YFF5                      | R1-R9                        |
| 14000 TADs         | Based on age of SNF            | OFF                       | R1-R9                        |
|                    |                                | YFF10                     | R1-R9                        |
|                    |                                | YFF5                      | R1-R9                        |

A total of 162 scenarios were considered for the analysis reported in Chapter 3 and 4. The subset of 27 scenarios was repeated 6 times, grouped as two sets of three. These sets assume that assemblies were removed from the pool before dry storage is removed and vice versa. The three options within each set follow one of the orders for dry storage removal: (1) TADs first, (2) DPCs first, or (3) a proportional amount. Total receipt rate is limited to 250 TADs per year and total capacity is limited to 7,250 instead of 7,500 so that the model results could be better compared to DOE's assumptions in the Preliminary Hazards Analysis (DOE 2006b). DOE assumes that 1,571 site-specific TADs and 5,676 utility TADs, about 7,250 total TADs, would be processed at YM. Receipt rate is documented to be anywhere from 250-300 TADs per year in the 2005 TSM study (BSAIC 2005).

## **Validation**

Several test cases were performed during model development to ensure that there were no errors in programming. These are described in terms of the different functions performed by the model.

### *Thermal Power Output Calculation*

A sample assembly thermal decay output can be calculated in a Microsoft Excel spreadsheet and compared with the GoldSim output from the Lookup tables stored in the array Current Heats for several values of burnup, enrichment, and years out reactor. This can be performed to ensure that the Lookup Table function is properly interpolating between values.

### *Loading Algorithms*

Several hypothetical pool scenarios can be created to test the three loading algorithms of OFF, YFF10 and YFF5. A test case can be created within a PWR pool. For any hypothetical case, the variable values can be tracked over time by checking the Time History box in the variable dialog. This allows for easily checking the history of the simulation to verify that the model is working correctly.

The following discharge dates and assembly counts should be used, while setting the pool capacity to 230, the repository year to 2020 and the year the TAD is available to 2010.

| Cycle Group | Count Assembly Start | Date Loaded |
|-------------|----------------------|-------------|
| 1           | 21                   | 33602       |
| 2           | 21                   | 33969       |
| 3           | 21                   | 34334       |
| 4           | 21                   | 34699       |
| 5           | 21                   | 35064       |
| 6           | 21                   | 35430       |
| 7           | 21                   | 35795       |
| 8           | 21                   | 36160       |

| 11          | 21                   | 37256       |
| 12          | 21                   | 37621       |
| 13          | 21                   | 37986       |
| 14          | 21                   | 38352       |
| 15          | 21                   | 38717       |
| 16          | 21                   | 39082       |
| 17          | 21                   | 39447       |
| 18          | 21                   | 39813       |
| 19          | 21                   | 40178       |
| 20          | 21                   | 40543       |
| 21          | 21                   | 40908       |
| 22          | 21                   | 41274       |
| 23          | 21                   | 41639       |

The burnup and enrichment of the cycle groups should be set to the same values so that the pattern in thermal heat output can easily be recognized over time for all assemblies.

The transportation heat limit should be set to a value that allows a canister to be fully loaded with 5 year old fuel assemblies. This total limit will depend on the enrichment and burnup values chosen for the cycle group, but will be much higher than any realistic value so it could just be set to an extremely large number ( $1 \times 10^6$ ) for this test case. If zone loading is turned off, then the total limit will be the thermal decay limit for

one 5 year old assembly multiplied by the number of assemblies in the canister. For example, a 40 GWd/Mtu burnup and 4% enrichment PWR assembly will be approximately 2,200 kW at 5 years, equal to a total limit of 46,200 kW. If zone loading is turned on, then the thermal decay limit should be high enough to allow the hot assemblies to be 5 years old.

The simulation should be run from the year 2002 to 2015. One container will be loaded each year to keep up with the discharges that occur each year. This will continue until the pool is empty in 2015. In (Container Location), the containers loaded before the TAD are marked as a 4 and the ones that are loaded after 2010 are marked as a 3.

If the Loading Transport variable is set to OFF, the discharge cycle groups will be emptied starting with the first discharge group and working toward the cycle groups that were discharged more recently.

If the algorithm is set to YFF10 or 5, the cycle groups will be emptied starting with the most recent that is at least ten or five years old, respectively. This will be the 6<sup>th</sup> cycle group for YFF5 and the 1<sup>st</sup> group for YFF10 if the data listed above is used. The next TAD will use assemblies from the 7<sup>th</sup> or the 2<sup>nd</sup> cycle group and so on, since the discharge groups are spaced one year apart. The cycle groups that the containers were pulled from can be viewed in Container Matrix.

To test the container loading functions after YM is open, set the capacity equal to  $1 \times 10^6$ . This will prevent any loading before YM opens. The simulation should be run from 2002 to 2025, with the repository set to open in 2020. From 2002 to 2020, no containers will be loaded. From 2020 to 2025, two containers will be loaded each year.

*Balancing Assembly Inputs and Container Outputs*

The count of assemblies within each cycle group at the start of the simulation in the array (Count Assembly Start) can be matched to the sum of the assemblies counted as removed from the cycle group. The sum of each row of the ContainerMatrix for each pool is equal to the total number of assemblies in the container for the fuel type, 21 or 44. ContainerMatrixRow sums the rows, so this final array value can be checked to match 21 or 44 in each cell.

The total number of assemblies discharged, which is the sum of the Count Assembly Start Vector, is checked to be equal to the sum of the number of assemblies loaded, the number of assemblies still in the pool, and the number of assemblies that may have been short loaded in the last canister.

The aggregate number of containers loaded among all the pools in Count Loaded is equal to the sum of Count After Cap, Count Aging DPC, Count Aging TAD, Count ISFSI, Count Emplaced DPC, and Count Emplaced TAD. If the simulation is set so that no containers are loaded, then the aggregate SumPool at a date after which all the assemblies have been discharged will be equal to the sum of the assemblies in the CountAssemblyStart Vectors for each pool.

## APPENDIX B

### STATISTICAL TEST RESULTS

#### Chapter 2 Results

##### *Effect of Trading Allocations Based on Least Remaining Capacity in SNF Pools*

##### Description of T-test

The paired t-test is applied to test if there is a significant difference in the mean of the response variable for paired values. Two sets of 9 subscenarios are matched, each with three samples (OFF, YFF, and YFF10), resulting in 27 total samples. The scenarios are identical except in one set of 27, the treatment is to allow trading and in the second one the treatment is to not allow trading. The comparison is blocked by the 9 subscenarios.

The null hypothesis is that the difference between the mean of the values in the population of the scenarios that do allow trading is not significantly different from the mean of the values in the population of scenarios that do not allow trading.

##### Description of T-test Output:<sup>1</sup>

The means comparison method can be thought of as determining if the actual difference in the means is greater than the difference that would be significant. This difference is called the LSD (least significant difference). The LSD term is used both for Student's  $t$  intervals and in context with intervals for other tests. In the comparison circles

---

<sup>1</sup> description taken from JMP Software Statistics and Graphics User Guide, Multiple Comparisons

graph, the distance between the circles' centers represent the actual difference. The LSD is what the distance would be if the circles intersected at right angles.

The top table is the Means Comparisons table, which shows all means comparisons with the differences between each pair. The groups are listed with the differences sorted in descending order. The difference in means in the upper right, the row mean( $i$ ), is farthest above the column mean ( $j$ ). There are zeros along the diagonal where each mean is subtracted from itself.

The bottom table is the difference between the absolute difference and the LSD that would be significantly different. If the values are positive, the difference is judged to be significant. The greatest differences are typically in the upper-right and lower-left corners, and the non-significant differences are generally down the diagonal of the table.

## Effect on Utility Site Storage

Response Variable: Expected aggregate demand for dry storage at the waste generation sites in the year that YM reaches current legal capacity. There are 3 samples for each subscenario, and 9 subscenarios for a total of 27 samples for each treatment of trading or no trading.

Dif=Mean[i]-Mean[j]

|     | No      | Yes    |
|-----|---------|--------|
| No  | 0.00    | 275.67 |
| Yes | -275.67 | 0.00   |

Alpha= 0.05

Comparisons for each pair using Student's t

| t       | Alpha |
|---------|-------|
| 2.01537 | 0.05  |

Abs(Dif)-LSD

|     | No     | Yes    |
|-----|--------|--------|
| No  | -14.12 | 261.55 |
| Yes | 261.55 | -14.12 |

Positive values show pairs of means that are significantly different.

| Level | Mean      |
|-------|-----------|
| No A  | 569.37037 |
| Yes B | 293.70370 |

Levels not connected by same letter are significantly different

Conclusion: Reject null hypothesis. The mean of the populations is significantly different with an alpha of 0.05.

## Effect on Transportation

Response Variable: Average number of pools sending shipments in a given year. There are samples for each year, covering a time span of 40 years, within each scenario. The time span covers a total of 40 years to accommodate for the variation in the opening date of the repository. This results in 40\*3 samples for each subscenario and 9 subscenarios, for a total of 1,080 samples for each treatment of trading and no trading. The test is blocked by subscenario.

| Dif=Mean[i]-Mean[j] |         |        |
|---------------------|---------|--------|
|                     | No      | Yes    |
| No                  | 0.000   | 11.156 |
| Yes                 | -11.156 | 0.000  |

Alpha= 0.05

Comparisons for each pair using Student's t

|  | t       | Alpha |
|--|---------|-------|
|  | 1.96140 | 0.05  |

| Abs(Dif)-LSD |         |         |
|--------------|---------|---------|
|              | No      | Yes     |
| No           | -2.0810 | 9.0680  |
| Yes          | 9.0680  | -2.0949 |

Positive values show pairs of means that are significantly different.

| Level | Mean      |
|-------|-----------|
| No A  | 31.345738 |
| Yes B | 20.189781 |

Levels not connected by same letter are significantly different.

Conclusion: Reject null hypothesis. Therefore, the mean of the populations is significantly different with an alpha of 0.05.

## Effect on Aging at YM

Response Variable: Number of years Aging Facility is occupied, pooling all assembly selection orders. There are 3 samples for each subscenario, and 9 subscenarios for a total of 27 samples for each treatment of trading or no trading.

Dif=Mean[i]-Mean[j]

|     | Yes     | No     |
|-----|---------|--------|
| Yes | 0.0000  | 4.6667 |
| No  | -4.6667 | 0.0000 |

Alpha= 0.05

Comparisons for each pair using Student's t

| t       | Alpha |
|---------|-------|
| 2.01537 | 0.05  |

Abs(Dif)-LSD

|     | Yes     | No      |
|-----|---------|---------|
| Yes | -1.7180 | 2.9486  |
| No  | 2.9486  | -1.7180 |

Positive values show pairs of means that are significantly different.

| Level | Mean      |
|-------|-----------|
| Yes A | 31.666667 |
| No B  | 27.000000 |

Levels not connected by same letter are significantly different.

Conclusion: Reject null hypothesis. Therefore, the mean of the populations is significantly different with an alpha of 0.05.

Response Variable: Number of canisters in Aging Facility, pooling all assembly selection order scenarios. There are samples for each year, covering a time span of 40 years, within each scenario. The time span covers a total of 40 years to accommodate for the variation in the opening date of the repository. This results in 40\*3 samples for each subscenario and 9 subscenarios, for a total of 1,080 samples for each treatment of trading and no trading. The test is blocked by subscenario.

| Dif=Mean[i]-Mean[j] |         |        |

|-------|-----------|
| Yes A | 603.40650 |
| No A  | 563.62873 |

Levels not connected by same letter are significantly different

Conclusion: Do not reject null hypothesis. Therefore, the mean of the populations is not significantly different with an alpha of 0.05.

## APPENDIX C

### DESCRIPTION OF MATERIAL TRANSFERS

#### Canister Receipt and Closure Facility Transfers

TADs arriving at the CRCF undergo 3 transfers:

- Transfer 1 involves one of the following, depending on the TAD's origin:
  - If the TAD arrives from the utilities, the *transportation overpack* holding the TAD will be loaded into the preparation area.
  - If the TAD is site-specific arriving from the WHF, the *shielded transfer cask* holding the TAD will be transferred from a cask transporter to the preparation area.
  - If the TAD is site-specific arriving from the Aging Facility, the *aging overpack* holding the TAD will be transferred from the cask transporter to the preparation area.
- Transfer 2: the TAD is transferred to the WP.
- Transfer 3: the TAD inside an unsealed WP is installed on the bedplate of the waste package transporter and sent to be emplaced. A trolley moves the WP to the closure cell where the WP is sealed. The WP is then moved with the same trolley to the load-out cell where it is rotated to a horizontal orientation and pushed into the Transport Emplacement Vehicle (TEV) which moves the WP to the underground.

## Wet Handling Facility Transfers

DPCs arriving at the CRCF undergo up to 4 transfers:

- Transfer 1: the transportation cask, shielded transfer cask, or aging overpack holding the DPC is moved from a cask transporter to the preparation area.
- Lid Lift 1: the lid of the transportation cask, shielded transfer cask, or aging overpack is removed *prior* to the DPC transfer.
- Transfer 2: the DPC is transferred from an aging overpack to a shielded transfer cask.
- Transfer 3: the shielded transfer cask holding the DPC is transferred to the cask cooling area.
- Lid Lift 2: the lid of the shielded transfer cask is installed *after* transfer of the DPC.
- Transfer 4: the shielded transfer cask holding the DPC is transferred from the cask cooling area to the pool.

TADs originating in the WHF undergo 4 transfers:

- Transfer 1: the shielded transfer cask holding the TAD is transferred from the pool to the drying/sealing area.
- Transfer 2: the shielded transfer cask holding the TAD is transferred from the drying/sealing area to a loading area.
- Transfer 3: the TAD is transferred from a shielded transfer cask to an aging overpack.
- Transfer 4: the aging overpack is transferred to a cask transporter and sent to the Aging Facility. (DOE conservatively assumes that all TADs originating in the

WHF are aged before they are emplaced because of the uncertainty involved in determining the heats of the TADs coming out of the WHF. If the Site-specific TAD is not aged, there is one less transfer in the WHF because the canister is sent straight to the CRCF in the shielded transfer cask via a cask transporter.)

### **Receipt Facility Transfers**

For vertical DPCs or TADs arriving at the RF:

- Transfer 1: the transportation cask holding the TAD or DPC is moved to the preparation pit.
- Lid Lift 1: the lid of the transportation cask is removed prior to DPC transfer.
- Transfer 2: the TAD or DPC is transported to an aging overpack.
- Lid Lift 2: the lid of the aging overpack is installed after transfer of the DPC.
- Transfer 3: the aging overpack is transferred to a cask transporter. It is likely that the drop height for such a lift would be small, and therefore not conducive to a DPC breach. Still, conservatively, a drop during this transfer is considered to cause a breach.

For horizontal DPCs arriving at the RF:

- Transfer 1: the transportation cask is transferred to a site transporter (in a horizontal orientation), the transporter moves the DPC within the transportation cask to the aging pad, and the DPC is pushed into a horizontal storage module.

### **ABSTRACT**

The development and preliminary use of an integrated model to explore the impact of various operational scenarios of the pre-closure waste management system of Yucca Mountain (YM) is described. The capabilities of the model are illustrated by applying it to a simplified operational scenario using Transport, Aging, and Disposal (TAD) Canisters. The application uses existing data on spent nuclear fuel to model the effect on above ground aging at YM by varying four parameters: (1) utility loading behavior, (2) thermal limit for transportation casks, (3) thermal limit for emplacement, and (4) emplacement capacity at YM. Results show that the thermal limit for emplacement is the most important parameter with respect to above ground aging demands at YM. Transportation heat limit is also important, but less so if the capacity of YM is expanded or if older fuel is sent first. Easing the constraint of the emplacement limit, if feasible, would be a preferable method of reducing aging demands, especially under an expanded emplacement capacity. Consequently, there may be incentive for Department of Energy (DOE) to either specify a lower transportation limit or a higher emplacement limit if it wishes to reduce the potential demands on the Aging Facility at YM.

### **INTRODUCTION**

The pre-closure waste management system of Yucca Mountain (YM) is defined as all components, facilities, and activities that collectively manage the spent fuel as it is packaged at the utilities, transported to the repository, processed at the YM surface facilities, and emplaced in the repository. In order to perform smoothly, this system requires long-term planning and cooperation of the spent fuel generators and the Department of Energy (DOE) among other parties (e.g. transportation and storage cask vendors, local and federal regulatory authorities). One must consider the motivations arising from the perspective of waste generators, as well as DOE, to evaluate the potential outcome of various design and operating scenarios.

---

## **Transport, Aging, and Disposal Canister**

DOE has announced a change to the design of the pre-closure system, requiring the operators of facilities in possession of spent nuclear fuel to use a Transport, Aging and Disposal (TAD) Canister to transport shipments of commercial spent nuclear fuel to YM. Prior to this decision, spent fuel assemblies would have arrived either in bare-fuel transportation casks, or in Dual-Purpose Canisters (DPCs), which can be used for transportation and storage, but not disposal [1].

Since the TAD will be used in a variety of applications, it will be governed by several regulations. For example, a TAD loaded and welded at a nuclear power plant will be governed by 10 CFR 50. If the TAD is placed in an Independent Spent Fuel Storage Installation for interim storage, it will be regulated under 10 CFR 72. A TAD placed in an certified over-pack and transported is licensed under 10 CFR 71, while a TAD placed in an over-pack for aging at YM will fall under 10 CFR 63.

To ensure that the TAD is developed according to the requirements of 10 CFR 63, DOE, as opposed to the vendors, specifies the design of the canister. The final design specifications for the TAD were released in 2007. These design specifications will guide vendors as they prepare license applications for the TAD under 10 CFR 71 (transportation) and 10 CFR 72 (storage). It is important to note that the design specifications do not stipulate a specific thermal limit for transportation or storage, but rather provide cladding temperature determination for total thermal outputs of 11.8 kW, 18 kW, or 25 kW. Once the TAD is licensed under Part 71 and 72, utilities can begin using it for storage and transportation. DOE will submit a license application under Part 63, which will describe their use of TADs in the overall design. NRC will determine if the TAD is important to safety in its review of the license application for YM. Specifically, the agency will determine if there are attributes of the TAD that are important to waste isolation, and conversely, if there are attributes of the design that have a detrimental effect on the post-closure performance [2].

The original YM pre-closure design called for *all* the fuel assemblies to be repackaged at YM. DOE changed the design to reduce the number of bare-fuel assembly handlings that would be necessary. While use of the TAD does reduce the number of expected nuclear material handlings, as well as the expected exposure of bare commercial spent nuclear fuel to a potentially oxidizing environment, it creates a potential problem in terms of thermal management. Before any final disposal package, referred to as a Waste Package (WP), can be emplaced in YM, its total thermal heat decay must fall below a specified emplacement limit. The emplacement limit is defined as 11.8 kW in YM design documents, but ongoing studies are exploring the possibility of easing this constraint up to 18 kW or even higher [1,3]. Any packages not meeting the specified limit must be stored above ground until the contents decay to a value below the emplacement limit.

The Nuclear Waste Technical Review Board has expressed concern that the decision to use the TAD canister may impact the thermal management strategy of pre-closure operations, mainly due to the fact that the utilities, as opposed to DOE, will now decide how to blend the fuel assemblies into the *final* disposition canisters. The utilities' discretion to blend fuel to their preferences reduces DOE's control over the thermal decay heats of the packages as they are being prepared for emplacement in the mountain [4].

### **Spent Fuel Delivery Schedule**

Utilities have a fair amount of freedom as to which individual fuel assemblies they load into TADs for transport (so long as they follow the procedures specified in the license documentation for the TAD canister), but they are guided by the Nuclear Waste Policy Act (NWPA) of 1982 when setting delivery schedules for shipments to YM. The NWPA authorizes the Secretary of Energy to develop a general contract with the owners and generators of the spent fuel [5]. The *Standard Contract for Disposal of Spent Nuclear Fuel and/or High-Level Radioactive Waste* (Standard Contract) provides for the acquisition of title to the spent nuclear fuel, its transportation to Federal facilities, and its subsequent disposal [6].

The Standard Contract states that spent fuel must be at least five years old to qualify to be sent to YM. Also, for every year after the repository starts accepting waste there is a specified allocation, measured in metric tons, which each waste generator is expected to send. The term "Purchaser" is used in the contract to refer to a spent fuel generator that has been paying into the Nuclear Waste Fund. A single Purchaser may own anywhere from one to many facilities, depending on the size of the Purchaser's corporation. Allocations given to each Purchaser are detailed in the Acceptance Priority Ranking (APR) and Annual Capacity Report (ACR) developed by DOE. The queuing order (APR) is based on the date the spent nuclear fuel was permanently discharged, giving priority to the oldest spent nuclear fuel, on an industry-wide basis. This order is combined with the annual rate of acceptance for YM to calculate the annual allocations for each Purchaser [7].

Allocations in the APR/ACR Report are not contractually binding on either DOE or the Purchasers. Instead, they are meant to assist Purchasers' planning and submittal of Delivery Commitment Schedules (DCS), which specify what fuel they intend to send and the delivery dates for the shipments. The legal requirements of the DCS allow for back and forth negotiations between DOE as outlined in Article V of the Standard Contract. Purchasers must submit their schedules five years before the shipments are to be made, and DOE has three months to approve of the first submitted schedule. If DOE disapproves of the proposed schedule, the Purchaser has thirty days to revise the schedule. DOE then has sixty days to decide if the revised schedule is acceptable. If the revised DCS is not acceptable, the parties will negotiate a mutually acceptable contract. Specifically, Purchasers have the right to adjust the quantities of spent nuclear fuel by up to twenty percent and the timing of the delivery by up to two months in the negotiations[6].

Purchasers must submit the final negotiated DCS to DOE at least one year before the delivery date. *Still*, DOE may disapprove of the final schedule within forty five days, and a revised schedule may be submitted thirty days after notice of the disapproval. DOE then has another sixty days to approve of the final revised DCS. If the schedule is still not mutually acceptable, the Standard Contract calls for the parties to negotiate again. Six months before the delivery date, purchasers are permitted to *exchange* delivery committed schedules with other Purchasers as long as DOE approves of the exchange [6]. Clearly, the legal opportunity for extended negotiations opens the potential for delays in the system.

Ideally, through careful planning, the parties could create a schedule that facilitates operations of YM and needs of the waste generators. This brings motivation for analyzing the possible reasons for DOE to disapprove of a schedule. One such reason may be that DOE is unable to accept shipments over a certain thermal threshold because it would cause excessive amounts of packages to be stored above ground at YM. Another hypothetical reason DOE might disapprove a schedule is if YM surface facilities do not have adequate processing capacities to handle the ratio of package types (DPCs vs. TADs). The remainder of this paper describes a methodology that can be applied for systematically analyzing possible shipment schedule scenarios and preliminary insights resulting from its application.

## **DATA, ASSUMPTIONS AND METHODOLOGY**

The model provides an opportunity to perform analyses of various delivery schedules, while also exploring the effects of changing the transportation heat limit, the emplacement heat limit, and the planned capacity of YM. This analysis is meant to be a preliminary screening tool to evaluate the relative importance of these parameters with respect to above ground aging requirements at YM, and is not meant to predict a comprehensive set of all realistic performance outcomes. Simplifying assumptions about national fuel inventory characteristics, TAD availability, and repository operations are described below.

### **Spent Fuel Inventory Characteristics and Projections**

Inventory of spent fuel is taken from the Energy Information Administration RW-859 database from 2002 [8]. Projections of spent fuel after 2002 are assumed according to a methodology developed by DOE that assumes an annual fractional burnup increase of 0.01, up to a maximum burnup of 57 GWd/MTU for boiling water reactors (BWRs) and 62 GWd/MTU for pressurized water reactors (PWRs) [9]. Reactor shutdown dates are also assumed. We presume all reactors that are not currently planned for decommissioning are granted extensions to run for a full 60 years. But, we do not analyze scenarios in which new reactors are constructed. To simplify data requirements, the burnup, enrichment, and mass of assemblies are averaged within the same discharge group. Each year, the thermal decay heat of each assembly discharge group is

interpolated using tables for burnup, enrichment and number of years out of the reactor [10].

### **TAD Availability and Repository Opening**

Before the repository opens nuclear power plants are expected to load dry storage when their pools reach full capacity. Assemblies removed from the pool are loaded into DPCs until the TAD is available for use. At the earliest, the TAD will be available in 2012 but to accommodate for possible delays in the licensing process, and because the utilities may lack economic incentive to adopt its use, it is not assumed to be in use by all the facilities until the year 2016.

Yucca Mountain is assumed to open in 2025. DOE plans to submit a License Application (LA) to the U.S. Nuclear Regulatory Commission (NRC) in 2008. The earliest estimate for opening the repository is 2017, but further delays are expected [11]. The assumption regarding the timing of dry storage campaigns, TAD availability, and the construction of the repository are important because the age of the fuel largely determines its heat output, especially for younger fuel. Under these assumptions, approximately 6,400 metric tons, will be loaded into DPCs before the opening of the repository – the equivalent of about 800 TADs.

### **Allocations for Shipments of Spent Fuel**

Each year after the repository starts accepting waste, approximately 3,000 MTU of allocations, dictating the number of TADs each facility loads, are assigned to the Purchasers. Mergers and acquisitions have taken place since the APR/ACR was established in 2004, and it is not clear if Purchasers will adjust their contracts accordingly. In an attempt to account for allocation trading that might be facilitated by owner/operator consolidations since 2004, the Purchasers have been altered to resemble current corporate ownership. Allocations for waste delivery schedules are assigned to Purchasers according to the date of discharge but are measured in units of TADs (300 TADs/year) as opposed to metric tons since it does not make economical sense to send a TAD that is not fully loaded.

Purchasers are assumed to distribute the allocations among their facilities, giving priority to the oldest fuel (OFF), youngest fuel that is at ten years old (YFF10), or the youngest fuel that is at least 5 years old (YFF5). Each facility loads fuel from the spent nuclear fuel pool according to the same algorithm assumed for prioritizing allocations. As many as 10 TADs are permitted to be shipped from a single facility in a given year, since this is considered a reasonable amount for a facility to load during the shipping campaign. Assemblies are packaged into TADs according to a zone loading scheme, meaning that the assemblies in the center are permitted to have twice the thermal output as the assemblies on the perimeter, as long as the total heat limit remains within the thermal criteria for transport.

## Surface Facility Operations

Upon arrival at the repository, TADs that meet the emplacement limit are assumed to be emplaced immediately. If all 300 TADs arriving in one year were within the emplacement limit, processing constraints of the surface facilities may realistically prevent emplacement of all 300 in a single year. However, this application attempts to gauge the potential range of demand on the Aging Facility so processing constraints were not enforced. Any packages not meeting the emplacement limit are counted as in the Aging Facility. Sensitivity of the results to varying the transportation heat limit from 18 kW to 25 kW, and the emplacement heat limit from 11.8 kW to 18 kW are explored. The capacity of YM is either assumed to be its current 70,000 metric tons (about 7,500 TADs), or to be extended to the amount required for holding the entire spent fuel inventory projected for all the reactors if they run for a total of 60 years.

## RESULTS

Results show that emplacement heat limit is the most important variable with respect to aging above ground at YM in terms of peak aging capacity needed, as well as the length of time fuel remains in the Aging Facility. Transportation heat limit also has a clear influence over above-ground aging at YM. As seen in the Fig. 1, the largest effect is seen when emplacement heat limit is lowered from its central value of 14.9 kW to 11.8 kW, assuming youngest fuel is sent first. Both transportation and emplacement criteria become less important if older fuel is sent in place of younger fuel.

**Fig. 1 Importance chart illustrating the relative change in maximum number of TADs aging above ground due to a change in heat limit for emplacement or transportation under various waste acceptance scenarios.**

Easing the emplacement heat limit constraint is a way to decrease the above-ground aging that does not impact delivery schedules since emplacement criteria drives the routing of packages *after* it arrives at the surface facilities. Transportation heat limit, on the other hand, governs the characteristics of the fuel *before* it is shipped to YM. Therefore, decreasing the transportation heat limit to a value that is lower than what is common (i.e., 18 kW as opposed to 25 kW) should only be considered a practical way of reducing the aging required at YM if it *does not* prohibit facilities from sending shipments that would have been sent under a traditional transportation heat limit.

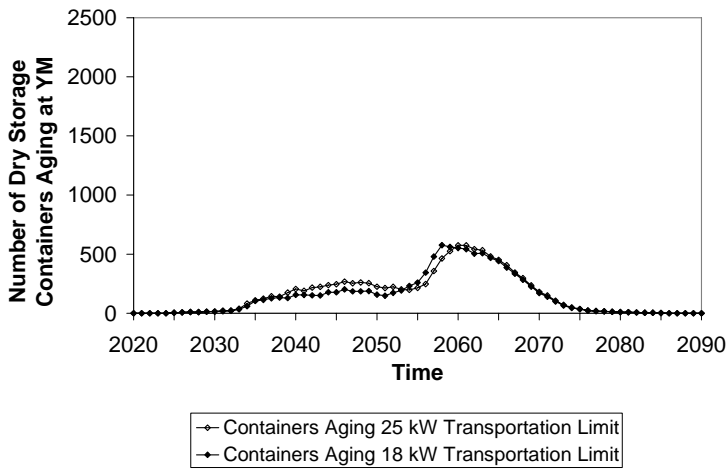

**Fig. 2 Impact on decreasing the transportation heat limit from 25 kW to 18 kW on above-ground aging if youngest fuel is sent first, assuming the current YM Capacity.**

Fig. 2 shows the amount aging above ground as the transportation limit is varied from 18 kW to 25 kW, while holding the emplacement limit at its central value of 21.5 kW. Note how the peak capacity aging above ground is effectively reduced from about 1,800 TADs to 800 TADs and the longevity of the Aging Facility is shortened by about 10 years. The rate of shipments (not shown in Fig. 2) is not changed by altering the transportation limit. This implies that there are enough cool assemblies in the Purchasers' inventories to fulfill a receipt-rate of 300 TADs per year for the entire shipping campaign under the current capacity of YM, even if the transportation heat limit is set to a lower level than what is common. However, the same is not true if the legal capacity of YM is expanded.

**Fig. 3 Impact on decreasing the transportation heat limit from 25 kW to 18 kW on above-ground aging if youngest fuel is sent first assuming an expanded YM Capacity.**

Fig. 3 shows the same information as Fig. 2 but assumes an expanded capacity of almost 140,000 metric tons. These scenarios shown assume that youngest fuel (at least 5 years old and meeting the per-assembly heat limit) is sent first. The maximum capacity of the Aging Facility is reduced, but the longevity of the Aging Facility is similar in both scenarios, implying that altering the transportation limit is not as effective at reducing the demands on the Aging Facility under an expanded capacity.

**Fig. 4 Impact on decreasing the transportation heat limit from 25 kW to 18 kW on above-ground aging if oldest fuel is sent first and assuming an expanded YM Capacity.**

Fig. 4 shows an expanded capacity but assumes that oldest fuel is sent first. During the first 10 years, the demands on the Aging Facility are largely similar under both scenarios. Starting around 2035, the curve for the 25 kW transportation limit scenario begins to exceed that of the 18 kW limit. This is because packages are taken from the dry storage pad at the waste generation sites in the 18 kW scenario, whereas in the 25 kW scenario facilities continue to load hotter fuel from the pool. After the first 30 years, there is a large increase in the number of packages that need to be aged, resulting from the fact that

much of the cooler fuel has been depleted from Purchasers' inventories. Assemblies being loaded are those that are newly meeting thermal criteria, and are therefore much hotter. The peak demand on the Aging Facility occurs around 35 years into the shipping campaign. These results suggest that decreasing the transportation limit is not as effective at reducing demands on the Aging Facility under an expanded capacity, especially if older fuel is sent first.

## **SUMMARY AND CONCLUSION**

The analysis described in this paper highlights inefficiencies of the existing allocation queue stemming from a recent decision to use the TAD canister. The existing method of assigning allocations as stipulated in the Standard Contract was developed prior to the TAD decision, and therefore does not adequately consider the ability of the utilities to optimally blend the waste according to Department of Energy's thermal management strategy. The TAD decision introduces uncertainty concerning the heats of *final* waste packages, causing potential for a highly variable capacity of the Aging Facility at the surface of YM.

The demand on the Aging Facility is minimal if the Purchasers send their oldest fuel first under the current capacity. However, Purchasers are not required to send their oldest fuel first and may prefer to send younger fuel depending on their spent fuel management strategy. If younger fuel is sent first, the aging above ground at YM can be reduced by reducing the thermal decay limit for transporting the TAD. If the legal capacity of YM is lifted to accommodate for substantially more spent fuel, however, reducing the transportation limit is less effective at controlling the demand on the Aging Facility.

In a future application of the model, the indicators of operational performance measured each year should be expanded to include the expected amount of dry storage necessary at each waste generation site as well as above ground storage at YM. In addition, the allocation queue should be dynamically created from feedback signals incorporating real-time inventories of the utilities and YM. Using this more comprehensive approach, future research could explore potential benefits achieved through alternative methods for Purchasers to prioritize allocations besides age of the fuel. The potential for Purchasers to trade allocations should also be analyzed, since the Standard Contract implies this is allowed. This will enable DOE and the Purchasers to explore whether a more efficient waste acceptance plan can be achieved.

## APPENDIX E

### THERMAL POWER OUTPUT TABLES

#### Description of Data Tables

The following tables contain the estimated thermal power output of a PWR or BWR assembly given: (1) the initial enrichment of the assembly, (2) the number of years the assembly has been out of the reactor, and (3) the final burnup (GW-d/MTU).<sup>1</sup> The mass is assumed to be 200 kg for BWR or 464 kg for BWR. The thermal power tables for PWR assemblies appear first, followed by the thermal power tables for BWR assemblies. Data are organized into tables for each enrichment level. Burnup values are organized into columns, with the rows representing the number of years the assembly has been out of the reactor. Thermal powers are provided in the cells of the table are in units of W/assembly. Thermal powers can be interpolated logarithmically between years out of reactor and linearly between enrichment and burnup values.

## **APPENDIX F**

### **MODEL OUTPUT RESULTS**

#### **Description of Data Tables**

The following tables contain the output data resulting from the analyses carried out for this research. The output from the 81 scenarios explored in Chapter 2 appears first, followed by the output from the 162 scenarios discussed in Chapters 3 and 4. Data is organized into tables for each response variable, with the name of the response variable centered at the top of the table. The scenarios are organized by columns, with each row representing a different calendar year of the simulation.

## Chapter 2 Scenarios

| Scenario ID | Allocation Trading Priority | Transportation Thermal Limit | Emplacement Thermal Limit | Utility Loading | YM Open Year | TAD Year | Allocation Trading | YMCap Number |
|-------------|-----------------------------|------------------------------|---------------------------|-----------------|--------------|----------|--------------------|--------------|
| 1           | Age                         | 21.5                         | 14.9                      | OFF             | 2025         | 2020     | 2                  | 7500         |
| 2           | Age                         | 21.5                         | 14.9                      | OFF             | 2025         | 2012     | 2                  | 7500         |
