*This work is dedicated to my family and friends, who have shown nothing but support for me in  
all of life's endeavors.*

## ACKNOWLEDGEMENTS

“As we express our gratitude, we must never forget that the highest appreciation is not to utter words, but to live by them.”

*- John F. Kennedy -*

There are many people I must thank for showing kindness, encouragement, and support for me during my tenure as a graduate student. First and foremost, I would like to thank my research advisor, Richard Caprioli, for providing both ample resources and guidance that allowed me to grow as a scientist. Our discussions about my research and science in general have helped me become a much more focused and discerning analytical chemist. I must also thank my Ph.D. committee members, Drs. Kevin Schey, John McLean, and Michael Stone, who have brought valuable insight into my research and provided direction along the way. My undergraduate advisor, Dr. Facundo Fernández, encouraged me to begin research in his lab and introduced me to the world of mass spectrometry. It was his motivation that drove me to pursue my Ph.D.

Every member of the Mass Spectrometry Research Center, both past and present, has guided me in some form or fashion. I would not be where I am today without the support of my “lab family”, both on a personal and scientific level. Maureen Casey was always there to brighten up the lab with humor and support. I will certainly miss going to see “Mama Maureen” and have her fix any problem almost immediately. Dr. Peggi Angel advised me as a rotation student when I first came to Vanderbilt and I strived to emulate her passion for science. Amanda Hachey, Salisha Hill, and Dr. Kristie Rose in the Proteomics Core could not have been more accommodating as I plunged into the vast field of proteomics. They were always there to share their wisdom, helping me learn new techniques that will be invaluable in my career. Drs. Megan

Gessel, Joshua Nicklay, Glenn Harris, Jeffrey Spraggins, and Boone Prentice have all been vital to my development as a scientist, acting as soundboards for ideas and encouraging me to enjoy successes and learn from failures. Whenever I needed to vent about science or life, they were there to listen. The fellow graduate students in lab who have seen me through this journey have left a lasting impression on me as well. They have always been there to lend a hand and I will truly miss seeing them in lab every day.

None of this would be possible without support from my family and friends. My mother, Robin, and father, Joe, encouraged me to pursue my love of science from an early age, even if that meant driving to enrichment programs early Saturday mornings. They taught me how to be a hard worker and independent person, but to never forget that no man is an island. Success and humility should never be mutually exclusive. My brother, Joey, and my sister, Meghan, continue to encourage me every day in everything that I do. Meghan has listened to the recap of my current state of life at day's end, and for that, I am eternally grateful. I cannot forget Rebecca Rosenberg, who has been a part of our family since the first grade. We have grown up together and will always be there to ground each other, no matter how far apart we are. My dogs, Marco and Polo, are the first things I see when I wake up and the last things I see when I go to bed. They've made the roughest days better, always showing excitement and affection when I get home (no matter how late that may be). Lastly, I would like to thank my entire extended family, including all of my aunts, uncles, and cousins. Though my grandparents could not be here to see this achievement, I know they would all be proud of such an accomplishment.

I must also acknowledge the funding support of grants from the NIH/NIGMS (5P41 GM103391-05 and 5R01 GM058008), the NIH Shared Instrumentation Grant Program (1S10OD012359-01), and a fellowship from Aegis Sciences Corporation.

# CHAPTER I

## INTRODUCTION

### **Matrix-Assisted Laser Desorption/Ionization Mass Spectrometry**

Mass spectrometry (MS) is a powerful technology that allows for the simultaneous measurement of multiple molecular species, with no *a priori* knowledge about the analyte required. Detection by MS is achieved by measuring an analyte's mass-to-charge ratio ( $m/z$ ), thus requiring the analyte to be ionized and have a charge. One such method of ionization is matrix-assisted laser desorption/ionization (MALDI) MS. First developed in the 1980s,<sup>1, 2</sup> MALDI is achieved by applying a matrix that absorbs at the wavelength of a laser and facilitates molecular desorption and ionization.<sup>3</sup> Both UV and IR lasers have been shown to be successful in MALDI experiments,<sup>4, 5</sup> though most current commercial instruments utilize UV lasers. Solid state lasers, such as frequency-tripled Nd:YAG and Nd:YLF, and nitrogen (N<sub>2</sub>) lasers are by far the most common lasers used in MALDI experiments.

The mechanism(s) of ionization during the MALDI process are still being investigated and debated, with evidence to support both the lucky survivor and gas phase protonation models.<sup>6</sup> Briefly, the lucky survivor model stipulates that analytes are incorporated into the matrix crystals with their respective charge states preserved from solution. The gas phase protonation model describes neutral analyte molecules undergoing gas phase collisions with charged matrix ions, leading to charge transfer and ionized analyte species. More extensive reviews can be found elsewhere for greater detail and empirical evidence.<sup>6, 7</sup>

There are a wide variety of matrices available that have shown to be effective in the analysis of different classes of biomolecules (Figure 1.1), such as dihydroxybenzoic acid (DHB) for lipids,<sup>8, 9</sup>  $\alpha$ -cyano-4-hydroxycinnamic acid (CHCA) for peptides,<sup>10, 11</sup> and sinapinic acid (SA) for proteins.<sup>12, 13</sup> Novel matrices are continuing to be discovered and synthesized to improve sensitivity and selectivity.<sup>14, 15</sup> While most are small organic molecules, unconventional matrices, such as graphite,<sup>1, 16</sup> nanoparticles,<sup>17, 18</sup> and ionic liquids<sup>19-21</sup> have also been utilized for specific analytes.

**Figure 1.1.** Structures of common MALDI matrices.(a) 2,5-dihydroxybenzoic acid – DHB; (b) 1,5-diaminonaphthalene – DAN; (c) 9-aminoacridine – 9AA; (d) 2,5-dihydroxyacetophenone – DHA; (e) 2-nitrophenol – 2-NPG; (f) 3,5-dimethoxy-4-hydroxycinnamic acid, or sinapinic acid – SA; (g) 2',4',6'-trihydroxyacetophenone – THAP; (h) 5-chloro-2-mercaptobenzothiazole – CMBT; (i)  $\alpha$ -cyano-4-hydroxycinnamic acid – CHCA.

## Imaging Mass Spectrometry

MALDI imaging mass spectrometry (IMS) enables the visualization of biomolecules in tissue by combining the sensitivity and selectivity of mass spectrometry with the spatially descriptive characteristics of classic histology. Originally described by Caprioli et al.,<sup>22</sup> the technology has been applied to the analysis of a variety of analyte classes, including pharmaceuticals,<sup>23, 24</sup> metabolites,<sup>25</sup> lipids,<sup>26</sup> peptides,<sup>11, 27</sup> and proteins.<sup>28, 29</sup>

Briefly, MALDI IMS experiments are performed by cutting fresh frozen or fixed tissue into thin sections and flat-mounting them onto a target. The sample is then coated with a MALDI matrix. This can be achieved by acoustically spotting matrix in discrete regions,<sup>30, 31</sup> spraying matrix onto the sample surface manually or robotically,<sup>28, 32</sup> or by employing dry coating techniques such as sublimation.<sup>9, 33</sup>

During acquisition, virtually defined regions of the tissue are irradiated by a laser in an array of discrete points generating a mass spectrum at each x,y coordinate. Typically, image spatial resolution is defined by the size of the laser spot on target and the spacing between the points in the array. Spectral intensities for a given ion are then plotted across the array, creating ion images that can be compared with stained images of the tissue providing an additional molecular dimension to classical histologic analysis (Figure 1.1).<sup>34</sup>

MALDI IMS of intact proteins is of particular interest because in a single experiment it has the potential to spatially describe the many endogenous proteoforms of a given protein, the various molecular forms which a protein product of a single gene can take (e.g., genetic variations and post-translational modifications).<sup>35</sup> However, protein imaging experiments have been hindered by the inability to structurally identify observed peaks, inhibiting the contextualization of IMS results with biological processes.

**Figure 1.2.** Schematic outline of a typical IMS workflow for fresh frozen tissue samples. Sample pretreatment steps include cutting and mounting the tissue section on a conductive target. Matrix is applied in an ordered array across the tissue section and mass spectra are generated at each x,y coordinate for protein analysis or tandem MS (MS/MS) spectra for protein identification. Reproduced from Ref. 32 with permission from Nature Reviews Cancer.<sup>34</sup>

## Fourier Transform Ion Cyclotron Resonance Mass Spectrometry

First, the definitions of mass resolution and mass resolving power must be established. Mass resolution refers to the separation (typically in Daltons) between two peaks in a mass spectrum. In figure 1.3a, this is represented by  $\Delta m_{50\%}$ , the peak full-width at half-maximum of the peak height. Mass resolving power factors in the specific  $m/z$  of the peak, calculated by  $(m/z)/\Delta m_{50\%}$ .<sup>36</sup> The superior resolving power of the Fourier transform ion cyclotron resonance (FTICR) mass spectrometers has been used to investigate drugs and metabolites,<sup>37</sup> lipids,<sup>38</sup> and peptides<sup>39</sup> in biological tissue samples, where near-isobaric species are able to be differentiated.

 Marshall AG, Hendrickson CL. 2008.  
Annu. Rev. Anal. Chem. 1:579–99.

**Figure 1.3.** Defining mass resolution and mass-measurement precision. (a) Two equal-magnitude mass spectral peaks of equal width, separated by one peak width at half-maximum peak height,  $\Delta m_{50\%}$ . Mass resolution is typically defined as  $\Delta m_{50\%}$ , whereas mass-resolving power is typically defined as  $m/\Delta m_{50\%}$ . (b) Relation between the mass-measurement precision predicted for the average of many measurements, and the signal-to-noise ratio and number of data points per peak width for a single mass spectrum. Reproduced from Ref. 34 with permission from the Annual Review of Analytical Chemistry.<sup>36</sup>

Additional figures of merit include mass precision and mass accuracy. Mass imprecision, denoted as  $\sigma(m)$ , accounts for the deviation of many mass measurements in a root-mean-squared

fashion. The mass precision is therefore the inverse of this value, or  $1/\sigma(m)$ . Mass precision can be practically calculated for most instruments by:

$$\text{mass precision} = c\left(\frac{S}{N}\right)\sqrt{\text{number of data points per peak width}}$$

where  $c$  is a constant that is determined by the peak shape. For FT instruments, the spectral baseline noise is independent of the signal.<sup>40</sup> A prediction of precision can therefore be made, using the S/N and sampling of individual measurements (Figure 1.3b). The last figure of merit discussed is mass accuracy. Mass accuracy describes the exact molecular mass of a particular analyte and how well the instrument is able to measure that exact mass.<sup>41</sup> Internal and external calibrations ensure minimal deviations from the expected measured value.<sup>42</sup>

Fourier transform ion cyclotron resonance (FTICR) mass spectrometers are examples of instruments with high figures of merit that have become more prevalent in the realm of MALDI MS over the past few decades.<sup>43-45</sup> These analyzers have remarkably high resolving power ( $10^5$  -  $10^6$ ) and high mass accuracy, typically on the order of low to single digit ppm errors.<sup>46</sup> Though the fundamentals are critical to fully understanding the power and scope of the instrument, they have been covered elsewhere at length.<sup>36, 46, 47</sup> Therefore, only the key concepts will be discussed and how they pertain to imaging mass spectrometry in particular.

Two essential components of the FTICR are a strong, fixed magnetic field and a cell that traps ions within this field. Ions will adopt a circular trajectory when they come into contact with the magnetic field, orbiting within the cell. This can be explained by centripetal and centrifugal forces for a given magnetic field ( $B$ ) and an ion velocity ( $v$ ):

$$\text{Centripetal force: } F = qvB$$

$$\text{Centrifugal force: } F' = \frac{mv^2}{r}$$

The forces will eventually balance, stabilizing the trajectory:

$$qvB = \frac{mv^2}{r}$$

$$qB = \frac{mv}{r}$$

Once the ion completes a full rotation, in a circular trajectory of  $2\pi r$  with a frequency

$$v = \frac{v}{2\pi r}$$

Therefore the angular velocity,  $\omega$ , is equal to:

$$\omega = 2\pi v = \frac{v}{r} = \frac{q}{m} B$$

Now simplified, the frequency and angular velocity depend on the ratio of  $(q/m)B$ .<sup>47</sup> This rotation, or non-coherent cyclotron motion, occurs within an ICR cell consisting of three sets of plates positioned opposite of each other: two excitation, two trapping, and two detection plates. As their names imply, the trapping plates are meant to keep the ions within the ICR cell during the analysis. The two excitation plates lying in parallel to the magnetic field apply a radio frequency (RF) current to the cell to excite the ions and cause them to coalesce into coherent ion packets with wider radii.<sup>48</sup> The ions do not collide with the detection plates, as seen in other mass analyzers, but rather induce a charge as they pass by, allowing for many measurements of the same packet(s) of ions (Figure 1.4a). The resulting readout is in a time-domain signal (Figure 1.4b), and a fast Fourier transform is performed to convert it into a frequency-domain (Figure

1.4c). Finally, a calibration of frequency-to  $m/z$  produces a mass spectrum with mass-to-charge ratios being plotted (Figure 1.4d).

Reproduced from Ref. 34 with permission from the Annual Review of Analytical Chemistry.<sup>36</sup>

## Spatially-Directed Tissue Collection Methods

Successful tissue-based proteomics experiments require the adequate extraction of proteins from very complex biological matrices. Traditionally, this has been achieved by homogenizing the tissue and performing solution-based extraction or enrichment prior to an LC-based separation.<sup>49-51</sup> This approach is very comprehensive in terms of total number of analytes detected, but any spatial component to the tissue is lost in the homogenization process. Furthermore, the dynamic range of proteins can span nearly seven orders of magnitude, while most modern mass spectrometers can only achieve up to four orders of magnitude in untargeted methods.<sup>52</sup> Proteins in high abundance will overshadow lower abundance species if not adequately separated, causing missed protein identifications.

One method used to provide a spatial component to the collection process is laser capture microdissection (LCM). Samples are observed through a microscope and regions of interest are marked for collection. These can be large regions of tissue, individual cells, or even intercellular components.<sup>53-55</sup> A finely-focused laser is used to then perforate the tissue region, then defocused to catapult the tissue into a collection device for down-stream analysis.<sup>56</sup> Figure 1.5 shows a schematic of this process as well as the very precise nature of collection achieved. The main disadvantage of this technology is the potential cost for equipment and upkeep. The required number of cells for a particular experiment is variable depending on the analyte, with rather large cell counts needed to successfully detect certain protein classes.<sup>57</sup>

Liquid-based collection strategies have also been developed to maintain spatial localizations during extraction. Manual microextractions have been used to target substructures within kidney and brain sections, using common lab materials such as pipettes and gel-loading tips.<sup>58,59</sup> Liquid extraction surface analysis (LESA) and liquid microjunction surface sampling

are similar approaches that utilize droplet contact to robotically extract analytes from the surface.<sup>60-62</sup> Most applications of the technology have spatial limitations of around 1mm, though this a major focus for future development.<sup>63</sup>

**Figure 1.5.** Implementation of laser capture microdissection (LCM). (a) Schematic of LCM collecting single cells from a tissue section. (b) Top – H&E stained section of tissue prior to LCM collection; Bottom – Same area post-LCM collection of 1.2 mm diameter circular region. Scale bar for (b) and (c) is 200  $\mu\text{m}$ . 1.5a was reproduced from Ref. 51 with permission from the International Journal of Molecular Sciences.<sup>56</sup>

The recent development of gel-based extraction methods have shown success from many biological tissues, both fresh frozen and formalin-fixed, paraffin-embedded.<sup>64, 65</sup> The polymers serve a dual purpose, both delivering reagents to the specific regions of tissue and extracting analytes for off-line analysis. The targeted digestion and extraction has even identified modified integral membrane proteins from brain sections.<sup>66</sup> Current fabrication methods create hydrogels with diameters of 1-3 mm, similar to both the manual and robotic liquid extraction methods.<sup>67</sup> A reduction of size while maintaining the high caliber of proteomic results would greatly improve the applicability of this approach in both the academic and clinical fields.

### **Traditional Protein Identification Approaches for IMS Experiments**

Protein identification strategies fall into three general categories; bottom-up, top-down, and indirect identification (Figure 1.6).<sup>68</sup> Bottom-up experiments involve enzymatic digestion of the protein mixture prior to analysis by mass spectrometry.<sup>69</sup> For imaging experiments, proteins are digested on tissue by applying an enzyme and performing hydrolysis in a way that preserves the spatial integrity of the proteins. Matrix is then applied, and both MS and MS/MS analyses are performed directly from tissue.<sup>70, 71</sup> Because MALDI ions tend to be singly charged, collision induced dissociation (CID) is often the method used for fragmentation. This approach can be advantageous because it extends the mass range of observable proteins by enzymatic digestion. Further, for most anatomic pathology examinations of biopsies, the tissue has been formalin fixed and paraffin embedded for preservation, and so bottom-up proteomics is the preferred procedure for analysis. The downside is that in practice, fragmenting peptides from tissue is hindered by the inability to effectively isolate ions from the considerable background signal and low fragmentation efficiencies for singly-charged peptides. Additionally, performing bottom-up

experiments in general may miss information regarding post-translational modifications (PTMs) if the modified peptide is not detected.

**Figure 1.6.** Schematic overview of ‘bottom-up’ and ‘top-down’ approaches employed for tandem mass spectrometry-based protein identification and characterization. The colored circles represent the amino acids of a protein, while the colored triangle and rectangle represent post-translational modifications. Reproduced from Ref. 47 with permission from the Royal Society of Chemistry.<sup>68</sup>

Top-down strategies<sup>72</sup> provide another approach for protein identification in IMS experiments. Here identifications are made through measurements of intact proteins followed by on-tissue MS/MS analysis. This approach is ideal for spatially describing the different proteoforms of endogenous proteins. However, similar to bottom-up experiments, on-tissue fragmentation of intact proteins is restricted by poor fragmentation efficiency for singly-charged proteins. Moreover, because most ions produced by MALDI have low charge states, electron-based fragmentation mechanisms (e.g., electron transfer dissociation) are often ineffective. Although work has been done to increase the charge state of ions generated from standards and tissue through matrix spotting approaches,<sup>73</sup> supercharging matrices<sup>74, 75</sup> or “ESI-like” surface analysis techniques<sup>76-80</sup> (e.g., LAESI, DESI, and MALDESI), further development is needed to improve image quality and sensitivity.

Indirect identification is an alternative approach that uses secondary information such as mass accuracy and spatial localization to link separate IMS and proteomics experiments. Because differences in preferential ionization between ESI and MALDI often lead to different peptides being detected, a direct link can be made between the two experiments by performing the analysis on intact proteins. Typically, protein images are collected using a linear time-of-flight (TOF) MS to accommodate for the relatively high  $m/z$  range. Then, with a serial section, proteins are extracted and analyzed using either top-down or bottom-up LC-ESI MS/MS based identification strategies. Protein extraction can be performed by homogenizing the entire section<sup>81, 82</sup> or by using spatially directed extraction technologies.<sup>83</sup> A major advantage of indirect identification is that it allows both the imaging and proteomics experiments to be operated under optimal conditions maximizing the sensitivity of both technologies. However, protein imaging using MALDI TOF MS does not provide the resolving power and mass accuracy

necessary to correlate imaging data to proteomics experiments with high confidence. Mass accuracies for MALDI TOF measurements are particularly skewed when collecting data directly from tissue, which introduces sample height differences and can promote surface charging attributable to the insulating nature of many tissues. In practice, the mass accuracy of a MALDI TOF protein imaging experiment is limited to 20–100 ppm, making identification based on mass accuracy unachievable. These negative sample surface effects on spectral quality are minimized when using decoupled mass analyzers such as FTICR, Orbitrap, and orthogonal TOF mass spectrometers.

### **Summary and Research Objectives**

The objectives of this dissertation are to develop robust analytical methods of MALDI FTICR IMS, both for peptides and intact proteins. This will be achieved through sample preparation and instrumentation improvements. The proper combination of matrix and solvent can be pivotal to improving signal from imaging experiments. An added benefit of the FTICR is that the source is at reduced pressure, meaning that volatile matrices that have shown promise on other platforms would be perfectly suited for the FTICR. There is a much lower risk of matrix subliming off of the sample and the ion optics are situated in a way that matrix accumulation would not interfere with the signal for longer acquisition time imaging runs. By incorporating high mass resolution and accuracy into a protein imaging platform, new biology can be investigated by looking at overlapping proteoforms or post-translationally modified species. Though traditionally mass-limited, the FTICR mass spectrometer has the capability of unambiguous protein identification by accurate mass when used in tandem with accurate mass fragmentation information. Additionally, the implementation of spatially-localized extraction

methods for protein identification has shown promise from previous iterations, but needs to be thoroughly evaluated and characterized before being incorporated into a routine assay. Hydrogel technologies are currently much larger than is required to accurately target many biological features. By improving the formulations, enzyme concentrations, and other factors within the hydrogel process, they will be able to be used in true histology-direct workflow with minimal interferences from surrounding regions of tissue.

**Objective 1:** Develop methods for direct tissue analysis of proteins on high-performance instrumentation such as FTICR mass spectrometers.

**Objective 2:** Assess the current methods of IMS-based protein identification by top-down and bottom-up methodologies, and improve identification confidence by incorporating spatially-driven proteomics.

**Objective 3:** Develop advanced hydrogel technologies capable of achieving sub-millimeter diameters while maintaining robust proteomic signal.

## CHAPTER II

### MALDI FTICR IMS OF INTACT PROTEINS: USING MASS ACCURACY TO LINK PROTEIN IMAGES WITH PROTEOMICS DATA

#### Introduction

Large portions of this section were adapted from J. M. Spraggins et al., *Journal of the American Society for Mass Spectrometry*, Copyright 2015 Springer<sup>84</sup> and J. M. Spraggins et al., *Proteomics*, Copyright 2016 John Wiley & Sons, Ltd.<sup>85</sup>

Fourier transform mass spectrometers, such as Fourier transform ion cyclotron resonance (FTICR)<sup>47</sup> and orbital trapping (Orbitrap),<sup>86, 87</sup> provide the highest mass resolution and accuracy of all mass analyzers. For imaging experiments, these high performance instruments routinely produce ion images with mass resolving powers greater than 50,000 ( $m/\Delta m$  50%) and mass accuracies better than 5 ppm.<sup>25, 37, 88</sup> These instruments are extremely valuable for tissue analysis where high resolving power is necessary to distinguish endogenous nominal isobars and high mass accuracy allows for more robust identification. Recently, accurate mass measurements (<5 ppm) have been shown to greatly increase the reliability of peptide identification by dramatically reducing the number of false positive identifications for IMS experiments using indirect identification strategies.<sup>89, 90</sup> FT-based IMS in combination with LC-ESI MS/MS has also proven to be useful for small molecule<sup>91</sup> and lipid analysis.<sup>88</sup> Neither FTICR nor Orbitrap platforms have traditionally been used for MALDI IMS of intact proteins because FT-based platforms have been  $m/z$  range limited. However, modern instrumentation (source ion optics) and access to

higher magnetic fields has dramatically improved the sensitivity and throughput of FTICR platforms at higher mass ranges.

## **Methodologies for MALDI FTICR IMS and Identification of Intact Proteins**

### *Tissue Preparation*

Fresh frozen rat brains and human clear cell renal cell carcinoma (ccRCC) samples were investigated due to the extensive literature surrounding protein IMS of these tissues using other mass analyzers and platforms.<sup>92-95</sup> Frozen tissue was sectioned to 10-12 microns and mounted onto conductive Indium-tin-oxide (ITO) coated slides (Delta Technologies, Loveland, CO, USA). Tissues were washed to remove interfering lipids and salts in sequential washes of 70% ethanol (30 seconds), 100% ethanol (30 seconds), Carnoy fluid (6:3:1 ethanol: chloroform: acetic acid) (2 minutes), 100% ethanol (30 seconds), ddH<sub>2</sub>O (30 seconds), and 100% ethanol (30 seconds).<sup>96</sup>

### *Matrix Application*

Matrix was applied using a TM Sprayer (HTX Technologies, Carrboro, NC, USA) with 15 mg/mL DHA in 9:1 ACN:ddH<sub>2</sub>O with 0.2% TFA. Sprayer conditions include a flow rate 0.1 mL/min, nitrogen flow of 10 psi, spray temperature of 80°C, a spray velocity of 1,100 mm/min, 4 passes with offsets and rotations, and 9:1 ACN:ddH<sub>2</sub>O as the pushing solvent. Samples were rehydrated as previously described<sup>97</sup> at 37°C for 3 minutes with 1 mL of 50 mM acetic acid as the rehydration solvent. This aids in the extraction of analytes into the matrix layer as the matrix recrystallizes.

## *MALDI FTICR IMS*

High mass resolution imaging experiments were performed using a 15T Bruker MALDI FTICR mass spectrometer (Bruker Daltonics, Billerica, MA, USA). The instrument is equipped with an Apollo II dual MALDI/ESI ion source and a Smartbeam II 2kHz Nd:YAG (355nm) laser. Data were collected from  $m/z$  1,100 – 25,000 with a data size of 1MB per spectrum. Special tuning of the Funnel RF amplitude (250 Vpp), accumulation hexapole (1.4 MHz, 1950 Vpp), transfer optics (1 MHz, 380 Vpp), time of flight delay (2.8 ms), and ICR cell (Sweep excitation power: 48%) were required for high  $m/z$  analysis. Although all parameters play a role in improving ion transmission through the source ion optics, tuning of the accumulation hexapole had the greatest impact on ion signal for high mass ions. External calibration was performed prior to analysis using CsI clusters. Ion images consisted of 13,596 pixels and 14,632 pixels for rat brain and ccRCC samples respectively. All protein identifications were made using mass accuracy (<5 ppm) of the highest intensity isotope by comparing MALDI FTICR IMS data to previously reported results or the compiled MSiMass database.<sup>98</sup>

## *Histology*

Immediately following MALDI IMS experiments, matrix was removed from samples using 100% ethanol and samples were hydrated through graded ethanol to ddH<sub>2</sub>O prior to using the Masson's Trichrome stain kit. Briefly, samples were incubated in a mordant solution, and then immersed in a Weigert's hematoxylin solution to stain cell nuclear contents black. A Biebrich Scarlet-Acid Fuchsin solution was used to stain acidophilic tissue components such as keratin and intercellular fiber red, and an aniline blue solution was used to stain collagen and

mucus blue. Optical images of stained tissue sections were obtained at 20x magnification using a Leica SCN400 Brightfield Slide Scanner.

#### *Protein Purification for Identification*

Rat brain was sectioned on a Leica cryostat and cerebrum was separated from cerebellum by a chilled razor blade. The cerebellum and cerebrum tissue sections were collected into corresponding pre-weighed Eppendorf tubes. At least 10 sections were combined into each tube before extraction was performed. An extraction solution composed of 25mM Tris (pH7.4), 50mM NaCl, and 0.25mM EDTA was made and approximately 350  $\mu$ L was pipetted into each tube. An ice-chilled homogenizer was used to homogenize the tissues, with 15–20 homogenization strokes used to liquefy the samples. A 150  $\mu$ L aliquot of each homogenate was taken and 1.53  $\mu$ L of acetic acid and TFA were added. The samples were homogenized again using the tissue homogenizer and set on ice for 30min with intermittent vortexing to avoid sample aggregation. Homogenates were spun down at 20,000 $\times$ g for 15 min and the supernatants collected. A Bradford assay (Thermo Scientific Pierce, Rockford, IL, USA) was used to quantify total protein concentration from each sample and the concentrations were adjusted to 2  $\mu$ g/ $\mu$ L with 0.1% formic acid for subsequent LC analysis.

#### *LC-Coupled Tandem Mass Spectrometry (ETD)*

Rat brain homogenate extracts were loaded onto a reversed phase capillary trap column using a helium-pressurized cell (pressure bomb). The trap column was packed with C<sub>8</sub> reverse phase material. Once the sample was loaded, the trap column was connected to a capillary analytical column equipped with a laser-pulled emitter tip and packed with 15 cm of C<sub>8</sub> material.

Using an Eksigent NanoLC Ultra HPLC, proteins were gradient-eluted at a flow rate of 500 nL/min, and the mobile phase solvents consisted of 0.1% formic acid, 99.9% water (solvent A) and 0.1% formic acid, 99.9% acetonitrile (solvent B). The gradient consisted of 5%–50% B in 55 min, followed by 50%–95% B in 8 min. Upon gradient-elution, proteins were mass analyzed on an ETD-enabled LTQ Orbitrap Velos mass spectrometer, equipped with a nanoelectrospray ionization source (Thermo Scientific, San Jose, CA, USA). The instrument was operated using a data-dependent method. Full scan spectra of  $m/z$  400–2,000 (resolving power: 60,000 at  $m/z$  200) were acquired as the initial scan event per duty cycle. For data-dependent scan events, the four most abundant ions in each MS scan were selected for fragmentation using ETD in the Velos ion trap. Dynamic exclusion was enabled allowing a repeat count of 1 within 20 seconds. ETD tandem mass spectra were acquired sequentially using the LTQ Velos ion trap followed by the Orbitrap (RP: 15,000 at  $m/z$  200) for mass analysis. An isolation width of 3 Da and an ETD reaction time of 80 ms were used for MS/MS spectra. The  $MS^n$  AGC target value in the ion trap was set to  $2 \times 10^4$ , the  $MS^n$  AGC target for Orbitrap scan events was  $8 \times 10^5$ , and the ETD reagent ion (fluoranthene) AGC target was set to  $1 \times 10^5$ .

### *Data Analysis*

Fragmentation spectra were *de novo* sequenced using Thermo Fisher Scientific Xcalibur™ Software and searched using BLAST databases. Once confident identifications were made, theoretical fragment ions produced from MS-Product within Protein Prospector (University of California at San Francisco) were matched to observed fragment ions within the spectra.

**Figure 2.1.** General sample preparation workflow for MALDI FTICR protein IMS and subsequent identification strategies using ETD fragmentation.

### MALDI FTICR IMS of Rat Brain as a Model System for Protein Imaging

For MALDI IMS, protein identification has traditionally been limited by poor sensitivity and fragmentation efficiency for on-tissue analysis or inadequate mass accuracy to effectively correlate imaging data with proteomics experiments using indirect identification strategies. As shown in Figure 2.2, MALDI FTICR IMS is capable of overcoming these challenges by producing imaging data of intact proteins with high mass resolution and accuracy. Initial analysis of rat brain tissue provided rich data with good sensitivity for ions up to  $m/z \sim 12,000$  (Figure 2.2a). The presented data, which are plotted as the overall average from the entire imaging experiment, were collected with a resolving power of  $\sim 40,000$  at  $m/z 5,000$  resulting in 2,123 peaks between  $m/z 2,000$  and 12,000 with  $S/N > 20$ . Expanding the intensity scale (Figure 2.2b) shows the overall complexity and quality of the data.

MALDI FTICR IMS provides the mass resolution necessary to distinguish protein charge states and overlapping isotopic distributions from neighboring ions (Figure 2.2c). The resolving

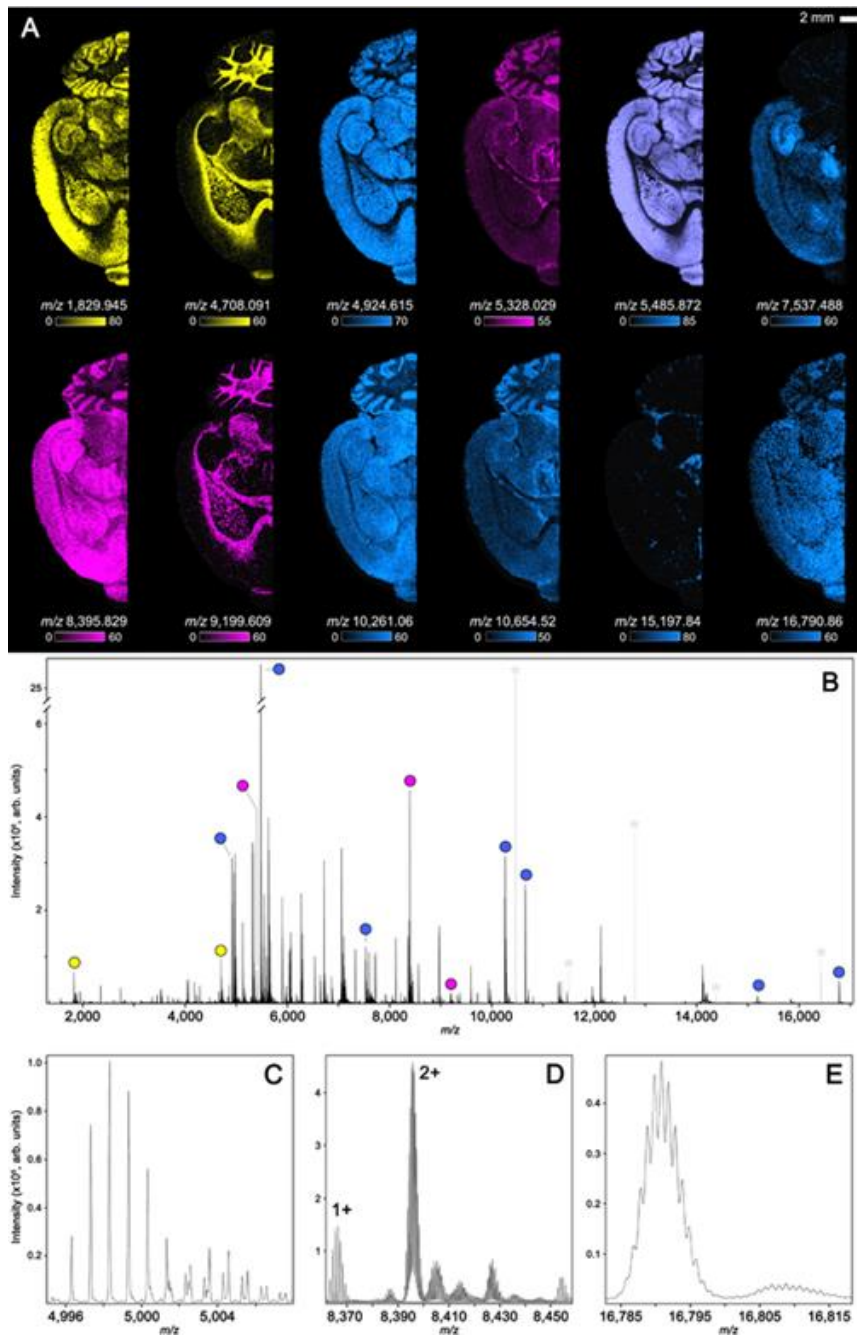

power of the experiment is more than sufficient to resolve the isotopic envelope for a given protein, enabling unambiguous assignment of charge state as demonstrated by the difference in isotope spacing between the singly charged ion labeled 1 (spacing: ~1.00 Da) and the doubly charged ions labeled 2 and 3 (spacing: ~0.501 Da). Although not all of the isotopic patterns were fully resolved, at least 10 different species can be discerned from the MALDI FTICR IMS results in just the 70 Da window spanning  $m/z$  5,630–5,700. It should be noted that, although at lower signal intensity, the singly charged ions of the proteins observed as doubly charged in this mass range were detected with  $m/z$  values >10,000.

**Figure 2.2.** MALDI FTICR IMS average spectra of intact proteins from transversally sectioned rat brain tissue. The average spectrum of the entire imaging data set is shown in (a). Expanding the intensity scale (b) highlights the overall complexity and quality of the data with singly and doubly charged protein signals detected between  $m/z$  1,000 and 12,000. Data were collected with a resolving power of  $\sim 40,000$  at  $m/z$  5,000 providing isotopic resolution and allowing ions of different charge states and modifications to be distinguished (c). The ion labeled 1 is singly charged and ions labeled 2 and 3 are examples of doubly charged ions. For comparison, MALDI TOF IMS data set collected in linear mode from a serial tissue section is displayed in (d). Electronic noise peaks are labeled (\*)

Figure 2.2d represents the average spectrum from a serial tissue section using MALDI TOF IMS in linear mode. These data are typical of most protein imaging experiments and clearly demonstrate the difficulty in making accurate identifications using low mass resolution IMS. Although reflectron TOF can provide higher mass resolution, at the expense of sensitivity due to the propensity for post-source decay,<sup>99</sup> linear MALDI TOF analysis was unable to resolve the complex mixture of overlapping proteoforms and proteins of differing charge states detected from rat brain tissue in this same  $m/z$  window ( $m/z$  5,630–5,700).

Additionally, peak shifts and broadening, likely due to surface charging or varying sample height, are clearly observed. MALDI FTICR platforms are not subject to adverse effects related to surface characteristics because the mass analyzer is decoupled from the ion source. However, TOF analyzers have a dramatic throughput advantage over FT-based platforms because pixel acquisition rates for FT instruments are generally limited by the scan time of the detection event. Although tunable, to maintain relatively high mass resolving powers, images are typically collected with scan times ranging from 0.5 to 2 s, limiting acquisition rates to ~2 pixel/s. TOF mass analyzers equipped with high repetition rate lasers, on the other hand, are limited by ion flight times that range from ~10 to 200  $\mu$ s and are able to rapidly produce ion images with acquisition rates that approach 10–30 pixel/s.<sup>100-102</sup> FTICR instruments can also suffer from space charge effects, limiting the observable dynamic range. This can be overcome using front-end accumulation techniques such as continuous accumulation of selected ions (CASI).<sup>103</sup> Both platforms have specific advantages for IMS experiments, but the ability of MALDI FTICR MS to produce ion images with high mass resolution and accuracy is ideal for imaging and identifying proteins from biological tissues.

**Figure 2.3.** MALDI FTICR IMS data collected from transversally sectioned rat brain tissue. Selected ion images (A) are color-coordinated based on charge state (Blue: 1+, Pink: 2+ and Yellow: 3+). The overall average spectrum for the 100  $\mu\text{m}$  imaging experiment is shown in (B) highlighting each peak used to generate the selected ion images (A). Expanded  $m/z$  windows (C–E) highlight the ability to detect proteins up to roughly  $m/z$  17,000 while providing the mass resolving power necessary to differentiate overlapping isotopic envelopes and determine protein

charge states. Electronic noise peaks have been greyed and marked (\*) to simplify the spectrum (B).

Figure 2.3 shows the capabilities of MALDI FTICR MS for protein imaging experiments. The analysis of rat brain tissue using MALDI FTICR IMS provided rich data with good sensitivity for ions up to  $m/z \sim 17\,000$  and proteins approaching 20 kDa (Figure 2.3a). The spectral data (Figure 2.3b–e), which are plotted as the overall average from the entire imaging experiment, were collected with a resolving power of  $\sim 70,000$  at  $m/z\ 5,000$ , resulting in 2,695 peaks between  $m/z\ 1,100$ – $17,000$  with  $S/N > 20$ . These data represent the largest ions detected from tissue using MALDI FTICR IMS with an  $m/z$  increase of  $\sim 5,000$  compared to previously reported results.<sup>84</sup> It is noted that this resolving power is not the theoretical limit of the spectral performance for MALDI FTICR protein imaging. For all experiments, resolving power is tuned to provide the performance necessary to resolve the target analytes but maintain the practicality of collecting imaging data. To achieve a resolving power of 70,000 at  $m/z\ 5,000$ , a time-domain signal of  $\sim 2$  s is required. Although detection events can be extended to increase resolving power further, the throughput of the experiment can become prohibitive for collecting ion images with large number of pixels.

The peak for each of the selected ion images is highlighted by the colored dots overlaid on the full-scan spectrum (Fig. 2.3b). Expanding the  $m/z$  scale (Figure 2.3c–e) shows the overall complexity and quality of the data. MALDI FTICR IMS provides the mass resolution necessary to distinguish overlapping isotopic distributions from neighboring ions (Figure 2.3c and d) and protein charge states (Figure 2.3d). The resolving power of the experiment is more than sufficient to resolve the isotopic envelope for a given protein, enabling unambiguous assignment of charge states as demonstrated by the difference in isotope spacing between the singly charged ion labeled 1+ (spacing:  $m/z \sim 1.0$ ) and the doubly charged ion labeled 2+ (spacing:  $m/z \sim 0.5$

Da). The same is true for higher  $m/z$  ions. Although not fully resolved, MALDI FTICR IMS can resolve the isotopic envelope even for a protein detected at  $m/z$  16,790.86 (Fig. 2.3e). Selected ion images are color-coordinated based on charge state (Blue: 1+, Pink: 2+ and Yellow: 3+).

Although protein identification was not the goal of this particular experiment, high-performance MALDI FTICR IMS also improves the ability to identify proteins observed in imaging experiments. High mass resolution IMS enables the differentiation between different proteoforms and provides the mass accuracy (<5 ppm) needed to link imaging data to orthogonal LC-based proteomics experiments and databases of previously identified biomolecules.<sup>84</sup> For example, the largest ion detected in this experiment was  $m/z$  16,790.864 (highest intensity isotope). Based on previously reported protein identifications from rat brain in imaging experiments,<sup>104</sup> it is most likely calmodulin (theoretical  $m/z$  16,790.847, ~1 ppm mass accuracy). Calmodulin is a  $\text{Ca}^{2+}$ -binding protein that activates several intracellular enzymes (e.g. kinases, phosphates and adenylyl cyclases) in cells.<sup>105</sup> In the brain,  $\text{Ca}^{2+}$ /calmodulin signaling is involved in processes such as neurotransmitter release, transcriptional regulation, and cell death.<sup>106, 107</sup>

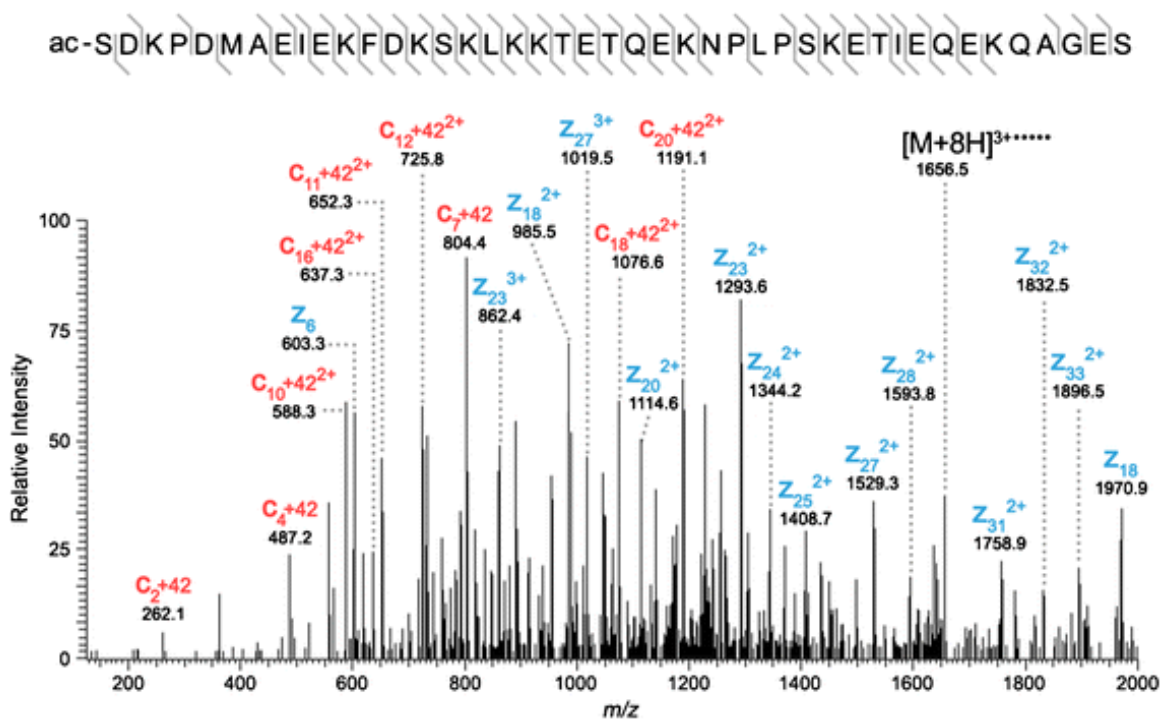

**Figure 2.4.** Selected ion images of identified intact proteins from rat brain tissue collected using MALDI FTICR IMS. Ions were identified using mass accuracy to correlate imaging results with separate top-down proteomics experiments. For comparison, the tissue was H&E stained following IMS analysis. Doubly charged ions are indicated in parentheses.

Figure 2.4 shows selected ion images at  $m/z$  4,936.536 ( $[M + H]^+$ ),  $m/z$  4,963.502 ( $[M + H]^+$ ),  $m/z$  5,636.074 ( $[M + H]^+$ ),  $m/z$  5,653.700 ( $[M + 2H]^{2+}$ , 11.3kDa), and  $m/z$  5,674.720 ( $[M + 2H]^{2+}$ , 11.4kDa). Imaging data were collected at a spatial resolution of 75  $\mu\text{m}$  (pixel spacing) with  $\sim 38,000$  total pixels. Even at this modest spatial resolution, substructures within the cerebellum (white matter, granular cell layer, and molecular layer) are clearly resolved. To minimize interference from overlapping isotopic patterns, images were plotted by selecting only the highest intensity isotope for each protein. Each of the presented ion images has a distinct spatial distribution within rat brain tissue. The ion at  $m/z$  5,636.074 is detected throughout the brain; however, within the cerebellum it can be found at higher intensities in the molecular layer. Ions at  $m/z$  5,653.700 and  $m/z$  5,674.720 are both found to be enriched in the granular cell layer of the cerebellum and proteins detected at  $m/z$  4,936.536 and  $m/z$  4,963.502 are absent from the cerebellum and primarily observed to be localized to the corpus callosum. For comparison, the tissue was stained by H&E following IMS analysis. All of the ion distributions are consistent with observed structures in the microscopy image.

Proteins highlighted in Figure 2.4 were identified using mass accuracy as the link between MALDI FTICR IMS data and LC-ESI top-down proteomics results. All top-down experiments were performed in high mass resolution mode (resolving power:  $\sim 60,000$  at  $m/z$  200) using standard identification strategies. The protein detected at  $m/z$  4,963.502 by MALDI FTICR IMS was identified as N-terminally acetylated thymosin  $\beta_4$  ( $T\beta_4$ -NtermAC, 0.1ppm). Top-down ETD data for the  $[M + 8H]^{8+}$  charge state of  $T\beta_4$ -NtermAC ( $m/z$  621.4440, 0.13ppm) can be found in Figure 2.5. The protein was determined to be acetylated on the N-terminus based on the observed mass shift of  $\sim 42.01$  for all observed c ions. The ion at  $m/z$  4,936.536 was determined to be N-terminally acetylated thymosin  $\beta_{10}$  ( $T\beta_{10}$ -NtermAC,

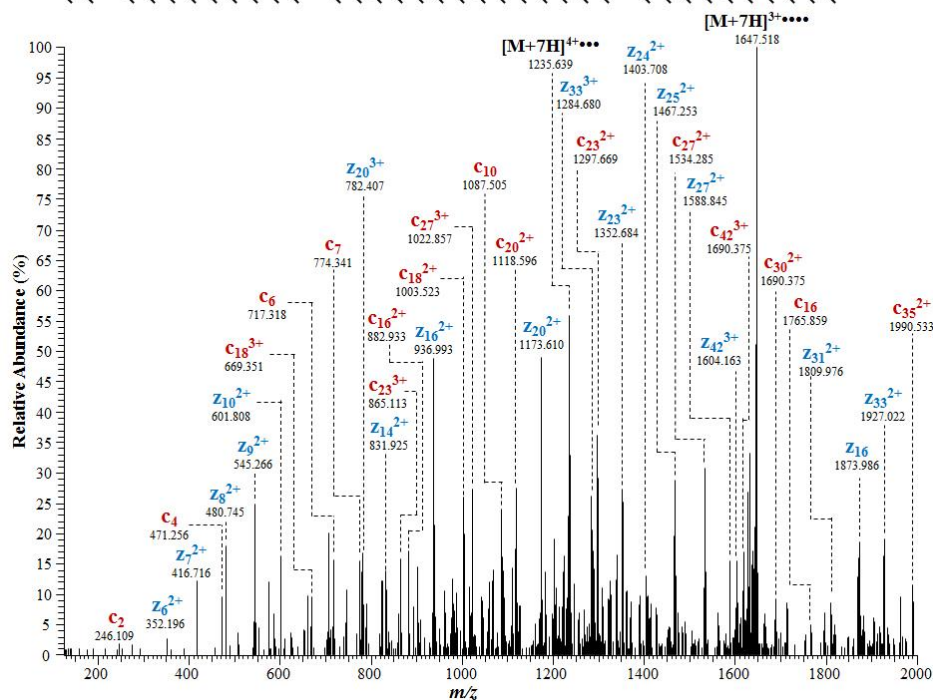

0.1ppm – Figure 2.6). Thymosin  $\beta$ 4 and  $\beta$ 10 are known to bind monomeric actin (G-actin) and regulate actin polymerization (F-actin). Controlled actin polymerization is essential for normal cytoskeletal function.<sup>108, 109</sup> The protein detected by MALDI FTICR IMS at  $m/z$  5,636.074 was identified as mitochondrial ATP synthase subunit  $\epsilon$  (ATPase- $\epsilon$ , -2.3ppm Figure 2.7). ATPase- $\epsilon$  is a subunit of the F1 complex of ATP synthase, a 500kDa protein found in mitochondria that is critical for production of ATP.<sup>110, 111</sup> The MALDI ions detected at  $m/z$  5,653.700 and  $m/z$  5,674.720 are both doubly charged proteoforms of histone H4; the first of which,  $m/z$  5,653.700, is acetylated at the N-terminus and the amino acid residue lysine 21 hypothesized to be dimethylated,<sup>112</sup> though the MS/MS data was unable to confirm this due to poor fragment ion peak signals (H4-NtermAC/K21Me2\*, -1.2ppm Figure 2.8). The ion at  $m/z$  5,674.720 is similar but has an additional acetylation of the lysine at position 17 (H4-NtermAC/K17AC/K21Me2 Figure 2.9). These fragmentation spectra were able to confirm the location of the dimethylation, corroborated with previously observed PTM locations in the Uniprot database. Histone H4 is one of five primary histone proteins that act as the structural core of nucleosomes. Histone H4 is known to undergo extensive acetylation and methylation, which is thought to control gene expression.<sup>113, 114</sup> MALDI FTICR IMS provides the mass resolution and accuracy needed to differentiate the complex mixture of proteins and their associated proteoforms while enabling identifications to be made with greater confidence than with traditional MALDI TOF experiments.

**Figure 2.5.** High mass resolution top-down ETD for the  $[M + 8H]^{8+}$  charge state of thymosin  $\beta 4$ . Selected c (red) and z (blue) ions are labeled clearly showing acetylation on the N-terminus. The amino acid sequence highlighting the fragmentation coverage is also provided.

### **Observed Protein Expression in clear cell Renal Cell Carcinoma (ccRCC)**

Cancer diagnoses of the kidney and renal pelvis are estimated to reach over 61,000 people in the United States in 2015, with roughly a 23% mortality rate.<sup>115</sup> Over 90% of these diagnoses will be of renal cell carcinoma, of which the majority will be clear cell renal cell carcinoma (ccRCC).<sup>115</sup> Detection and imaging of these tumors have typically been performed through computed tomography (CT) and magnetic resonance imaging (MRI),<sup>116</sup> though immunological and biomarker assays have become more prevalent in diagnostics.<sup>117</sup> Many ccRCC tumors are resistant to chemotherapy and radiation therapy, so nephrectomies still remain the gold standard of treatment with a greatly improved prognosis if the tumor is completely removed.<sup>118</sup> Unfortunately, visual and histological assessments of tumor margins can prove insufficient, with incomplete resections leading to disease recurrence.<sup>119</sup> Molecular localization patterns in and around the tumor can provide insight into the tumor microenvironment and aid in defining the molecular margin.<sup>94</sup>

MALDI FTICR IMS protein data collected from human ccRCC tissue is shown in Fig. 2.10. These data have similar figures of merit to the previously discussed rat brain FTICR IMS analysis. The average spectrum from the entire imaging experiment shows ions detected with good sensitivity up  $m/z \sim 16,000$  (Fig. 2.10b). The data were collected with a resolving power of  $\sim 75,000$  at  $m/z 5,000$  resulting in 4,051 peaks detected between  $m/z 2,000$ – $16,000$  with  $S/N > 20$ . An overlay of the proteins detected at  $m/z 5,653.732$ ,  $m/z 4,936.521$  and  $m/z 7,934.107$  show good correlation to tissue substructures visualized by histological staining (Fig. 2.10a). Hemoglobin subunit beta was detected at  $m/z 7,934.107$  (HBB,  $[M+2H]^{2+}$ , 4.7 ppm) and was observed throughout the kidney with regions of highest intensities near the tumor regions. Normal kidney functions include removing excess organic molecules from the blood through

small filtration units called glomeruli. However, renal cell carcinoma, like many other tumors, utilizes the process of angiogenesis to promote vascularization in and around the developing tumor. This in turn supplies the tumor with blood rich in nutrients for growth and proliferation.<sup>120</sup> Localization of hemoglobin to these regions likely corresponds to a highly vascularized carcinoma.

The ion observed at  $m/z$  4,936.521 was found to be N-terminally acetylated thymosin  $\beta$ 10 (Thy $\beta$ 10-AC,  $[M+H]^+$ , 3.0 ppm) and was localized specifically to the tumor region, with relatively low abundance in surrounding normal tissue. Thymosin  $\beta$ 10 organizes the cytoskeleton between cells by regulating the formation of actin polymers. The relative abundances have been shown to rapidly increase during the development of various cancers, including renal cell carcinoma.<sup>121</sup> Histones are core components of the nucleosome and regulate DNA repair and replication. They have been shown to have many post-translational modifications, effectively altering their function within biological systems. Histone H4 has been observed in relatively lower abundance in cancerous regions compared to normal tissue,<sup>122</sup> however recent work has shown that renal cell carcinoma and many other cancers can alter histone modification pathways, changing the post-translational modifications that are expressed.<sup>123</sup> The image of  $m/z$  5,653.732, determined to be histone H4 with an acetylation and dimethylation (HH4-AC/2Me,  $[M+2H]^{2+}$ , -4.4 ppm), shows an increased abundance in the adjacent normal tissue, with significantly lower signal in the tumor region.

A unique aspect of performing protein imaging experiments using MALDI FTICR IMS is the ability to both generate multiply charged ions using MALDI matrices such as DHA and then accurately determine the charge state of highly charged ions. Figure 2.10c-f show the ion images and isotopic distributions for the  $[M+H]^+$ ,  $[M+2H]^{2+}$ ,  $[M+3H]^{3+}$ , and  $[M+6H]^{6+}$  charge states of

**Figure 2.10.** Selected ion images of identified intact proteins from human clear cell renal cell carcinoma collected using MALDI FTICR IMS. Observed substructures in the overlaid 30  $\mu\text{m}$  ion image of  $m/z$  5,653.732 (HH4-AC/2Me,  $[M+2H]^{2+}$ , red),  $m/z$  4,936.521 (Thy $\beta$ 10-AC,  $[M+H]^{1+}$ , blue), and  $m/z$  7,934.107 (HBB,  $[M+2H]^{2+}$ , yellow), were consistent with the trichrome staining following IMS acquisition (A). The overall average spectrum for the 100  $\mu\text{m}$  imaging experiment is shown in B highlighting each peak used to generate the selected ion images (A). Ion images and isotopic distributions for the  $[M+H]^{1+}$ ,  $[M+2H]^{2+}$ ,  $[M+3H]^{3+}$ , and  $[M+6H]^{6+}$  charge states of hemoglobin subunit beta are shown in (C–F). Electronic noise peaks have been greyed and marked (\*) to simplify the spectrum (B).

hemoglobin subunit beta. Although the 2+ charge state is detected with much greater intensity, the other ions are still detected with good sensitivity. The generation of multiply charged ions using low mass resolution instruments can complicate spectral interpretation, particularly for complex samples such as biological tissues. However, the ability to produce highly charged ions using high resolving power instrumentation that can differentiate overlapping isotopic patterns to simplify interpretation is advantageous in moving larger proteins into the effective  $m/z$  range of the instrument. This potentially improves the capability of top-down fragmentation experiments directly from tissue.

### **Conclusions**

Imaging mass spectrometry is a highly sensitive and efficient discovery tool used to enhance classic histologic analysis by providing specific molecular detail. However, identification of detected proteins remains a significant challenge. Indirect identification is one of the most effective strategies for identifying molecules of interest in IMS experiments. By separately performing MALDI IMS and LC-MS/MS, each can be operated optimally for their individual tasks. Previously, this strategy has lacked sufficient mass accuracy in the imaging data to correlate the two approaches with high confidence. MALDI FTICR MS is now capable of overcoming this challenge by producing ion images with high mass resolution ( $\sim 75,000$  at  $m/z$  5,000) and accuracy ( $<5$  ppm) for proteins up to and beyond 16,000 Da. This has been achieved by carefully optimizing sample preparation methods as well as tuning instrument parameters to increase signal of higher molecular weight species. Analysis of control rat brain tissue and human kidney tumor tissue showed that protein charge states and complex mixtures of proteoforms were able to be distinguished, making identification more feasible and allowing these tissues to be studied with unprecedented molecular detail.

## CHAPTER III

### SPATIALLY-TARGETED EXTRACTIONS TO IMPROVE PEPTIDE IDENTIFICATIONS FROM MALDI FTICR IMS EXPERIMENTS

#### Introduction

While top-down proteomic approaches now provide a method for the identification of intact molecular species from tissue, many improvements still need to be made. Functional top-down databases are still relatively new,<sup>124, 125</sup> and have not had decades of curation as seen by larger genomic databases.<sup>126, 127</sup> Protein databases may not have all of the isoforms, splice variants, or post-translationally modified forms of the protein listed, as many are still unknown.<sup>128</sup> Additionally, many clinical samples are stored in tissue banks after formalin fixation and paraffin embedding. This process chemically cross-links the proteins within the sample, maintaining cellular histology and stabilizing them for long-term storage.<sup>129</sup> This process is irreversible, meaning that accessing proteins for proteomics or MALDI IMS requires an alternate approach.

Bottom-up approaches to proteomics rely on the enzymatic digestion of proteins into peptide components, bypassing the cross-linked nature of the formalin-fixed sample.<sup>130, 131</sup> Extensive literature exists on optimizing enzymatic digestion for specific samples, but it has been focused largely on in-solution digestions.<sup>132-134</sup> These strategies traditionally use homogenization to aid in the extraction of analytes, thus resulting in the loss of any spatial information from the sample. The procedures are effective, resulting in rich datasets for identifications but process can be extensive and require a relatively large amount of sample.

The introduction of *in situ* digestion of tissue samples has allowed for spatial information to be maintained while still providing peptide signatures for protein identification.<sup>11, 135</sup> Trypsin or other enzymes can be applied directly to the tissue, then the peptides can be analyzed by MALDI IMS or extracted for bottom-up identifications. The use of hydrogel technologies for this approach will be discussed in greater detail in Chapter IV. Regardless of the method, the goal of identifying peptides from specific regions of biological samples remains the same.

For MALDI peptide IMS experiments, time-of-flight (TOF) mass spectrometers have commonly been used due to the high sensitivity and dynamic range, large practical mass range, reasonable molecular specificity, and high throughput of the TOF analyzer.<sup>136</sup> Complex samples such as tissue provide many interferences, and the resolving power of TOF instruments can prove insufficient. Additionally, inherent mass accuracy differences between TOF imaging platforms and high performance LC-ESI-MS/MS require wide mass windows to match IMS spectral peaks to corresponding LC-MS/MS peaks for potential identification. By incorporating higher-performing instruments, such as FTICRs, into peptide imaging workflows, accurate mass measurements can be achieved.<sup>137, 138</sup>

## **Methodologies for Trypsin Application, *in situ* Digestion, Incubation and MALDI IMS for Peptides**

### *Tissue Preparation*

Fresh frozen rat brains and human clear cell renal cell carcinoma (ccRCC) samples were investigated because protein localization patterns were already investigated in Chapter II. Frozen tissue was sectioned to 10-12 microns and mounted onto conductive Indium-tin-oxide

(ITO)-coated slides. Tissues were washed to remove interfering lipids and salts as with the protein analysis.<sup>96</sup>

### *Trypsin Digestion*

Trypsin was applied to the tissue sections using a modified TM Sprayer, which allowed for lower rate applications. Matrix application flow rates are typically on the order of 0.1-0.5 mL/min, while the trypsin methods call for 7.5  $\mu$ L/min to allow for a relatively dry coating. This minimizes delocalization or enzyme “pooling” on the tissue surface. Samples were placed in an incubation chamber<sup>39, 96</sup> containing 100 mM ammonium bicarbonate, sealed with lab tape, and incubated at 37°C for 14 hrs. After incubation, samples were removed from the incubation chamber and dried in a desiccator prior to matrix application.

### *Matrix Application*

Matrix was applied using a TM Sprayer with 15 mg/mL DHA in 9:1 ACN:ddH<sub>2</sub>O with 0.2% TFA. Sprayer conditions include a flow rate 0.1 mL/min, nitrogen flow of 10 psi, spray temperature of 80°C, a spray velocity of 1,100 mm/min, 4 passes with offsets and rotations, and 9:1 ACN:ddH<sub>2</sub>O as the pushing solvent. This is the same method that was used to successfully image proteins by MALDI FTICR and therefore was chosen because of the robust signal. Samples were rehydrated as previously described<sup>97</sup> at 37°C for 3 minutes with 1 mL of 50 mM acetic acid as the rehydration solvent.

### *MALDI FTICR IMS*

High mass resolution imaging experiments were performed using a 15T Bruker MALDI FTICR mass spectrometer, as in Chapter II. Instrument tuning was performed in a similar fashion as before, though the mass range was limited to  $m/z$  5,000-8,000 to minimize the detection of electronic interferences. DHA provided robust peptide signal from tissue samples and resolving power was adjusted to maximize signal intensity and minimize unresolved peaks. External calibration was performed prior to analysis using CsI clusters and protein standards.

### *Peptide Extraction from Tissue*

Microextractions were performed for both proteins and peptides using 20% acetonitrile and a gel-loading pipette tip as previously described.<sup>83</sup> A 1  $\mu$ L solution was pipetted onto the tissue and repeated aspirated then withdrawn. This was repeated 3x and collected into 2  $\mu$ L of 20% acetonitrile.

### *LC-Coupled Tandem Mass Spectrometry*

Microextracts were loaded onto a reversed phase capillary trap column using a helium-pressurized cell (pressure bomb). The trap column was packed with C18 reverse phase material. Using an Eksigent NanoLC Ultra HPLC, proteins were gradient-eluted at a flow rate of 500 nL/min, and the mobile phase solvents consisted of 0.1% formic acid, 99.9% water (solvent A) and 0.1% formic acid, 99.9% acetonitrile (solvent B). The gradient consisted of 5%–50% B in 55 min, followed by 50%–95% B in 8 min. Upon gradient-elution, peptides were mass analyzed on a Thermo Q Exactive mass spectrometer, equipped with a nanoelectrospray ionization source. HCD tandem mass spectra were acquired in a top 20 data-dependent manner.

## Data Analysis

Tandem mass spectra were searched using SEQUEST software against the corresponding *Rattus norvegicus* or *Homo sapien* Uniprot database. Identified peptides were matched to their corresponding proteins and assembled in Scaffold 4.0 software. Confident identifications were made with protein identification probabilities of  $\geq 99\%$ , protein identification probabilities of  $\geq 95\%$ , and a minimum of 2 distinct peptides per protein.

**Figure 3.1.** General sample preparation workflow for MALDI FTICR peptide IMS and subsequent identification strategies using HCD fragmentation.

### Optimizing Incubation Conditions to Maximize Digestion and Minimize Delocalization

Though a great deal of research has focused on trypsin digestion, traditional approaches utilize in-solution digests, where the sample is dissolved into a solution containing the enzyme.<sup>133, 134</sup> The digestion conditions, such as buffer pH and concentration of enzyme present in-solution, can be easily maintained. These conditions become much more challenging for *in situ* trypsin digestion because digestion efficiency must be balanced with analyte localization.<sup>139, 140</sup> If analytes become delocalized in the tissue, then the spatial component is lost, thus negating the usefulness of such a technique. Discrete application of enzymes has proven successful

previously, minimizing the area analytes are able to delocalize within.<sup>11, 141</sup> However, delocalization can occur not only during the enzyme application step, but also during the incubation process. Efforts to minimize incubation times have proven successful with the introduction of microwave-assisted digestion.<sup>67, 142</sup> Alternatively, incubation chambers can be used to provide a humid environment for the tissue, and by extension the trypsin, to remain hydrated.<sup>39</sup> Since these are typically home-built, there is a great deal of variation that can be observed from method to method. To assess analyte delocalization during the incubation process, four serial rat brain sections were used. Each tissue was washed in an identical manner prior to trypsin application, and trypsin was applied to all four sections simultaneously using a TM Sprayer. The only difference in the four conditions was the amount of ammonium bicarbonate present in the incubation chambers.

After an over-night incubation, matrix was applied to all four sections at the same time and they were analyzed on a MALDI FTICR as one image to account for any normalization or visualization discrepancies that could occur. Figure 3.2 shows selected ion images of different peptides for each incubation condition. There are a few noticeable trends from this experiment that shed light onto the incubation process. The sample incubated with 50  $\mu$ L of 100 mM ammonium bicarbonate appeared to have the least amount of delocalization, when comparing the ion images to the histology of the rat brain. As the volume of ammonium bicarbonate in the incubation chamber increased, the localization patterns seem to degrade fairly rapidly. Conversely, there were peaks observed in the higher-volume ammonium bicarbonate incubations that showed little or no intensity in the 50 or 100  $\mu$ L conditions. This is most likely due to the fact that higher ammonium bicarbonate volumes led to a more humid environment in the incubation chambers. As these vapors condensed back down onto the tissue, this allowed for

optimal trypsin digestion to occur on the tissue surface. The lower volumes would not have provided the same level of moisture in the chambers, so therefore the efficiency of the digestion would have suffered, potentially leading to inactive trypsin or incomplete digestion. To balance digestion conditions and localization, incubation volumes of 50-100  $\mu\text{L}$  were chosen for subsequent experiments.

**Figure 3.2.** Utilizing MALDI IMS to aid in the assessment of enzymatic incubation conditions. Tissues were prepared and imaged in an identical manner, with only the volume of 100 mM ammonium bicarbonate in the incubation chamber being varied.

## MALDI FTICR IMS and Localized Peptide Analysis of Biological Samples

To properly assess on-tissue digestion efficiencies or presence of miscleavages, peptide identifications must be established. On-tissue fragmentation of peptides has been used in many instances with great success.<sup>92, 143</sup> However, throughput for this process is very low, and many instruments can be limited, either by the inherent nature of the instrument or low signal intensities. As discussed previously, indirect identification methods have proven to be very successful because each analysis is run with optimal conditions.

Traditionally, peptide identification has been achieved using homogenization and in-solution digestion.<sup>132</sup> This can add a level of variability though, because the digestion conditions would be different from an on-tissue digest. To minimize differences in peptides observed from MALDI IMS and LC-ESI-MS/MS approaches, the digestion should remain the same for both. This means performing the digestion *in situ*, then extracting peptides for subsequent LC analysis. Microextracts have already been shown to provide robust signal from localized regions of tissue,<sup>83</sup> and this approach was used to extract peptides from three different regions of rat brain post-digestion. The extracts were analyzed independently and compared to a traditional homogenization approach. Figure 3.3 shows the three regions that were chosen for extraction on the H&E section. When comparing the peptide and protein overlap between the regions, there are distinct analytes from each region that are not found in the other two. Table 3.1 shows the identities of these unique proteins from each region. This highlights the strength of a spatially-directed approach, focusing identification strategies only on the region of interest, rather than the tissue as a whole.

**Figure 3.3.** LC-MS/MS analysis of rat brain regions sampled by microextraction and tissue homogenization. Identifications were considered confident within Scaffold Proteome Viewing software when they had a 99.9% Protein Threshold, a 95% Peptide Threshold, and a minimum of 2 peptides.

70 Protein Identifications Unique to the "Microextracts":				
Description	Accession	Region 1	Region 2	Region 3
40S ribosomal protein S16	sp P62250 RS16_RAT	X		X

**Table 3.1.** Protein identifications from rat brain regions exclusively observed by microextraction analysis. Identifications were considered confident within Scaffold Proteome Viewing software when they had a 99.9% Protein Threshold, a 95% Peptide Threshold, and a minimum of 2 peptides.

While the rat brain does provide various substructures and spatial heterogeneity, a more complex sample was chosen to validate this approach. A human ccRCC tumor sample contained various stages of tumor progression, the adjacent normal tissue, and a margin in between these two regions. Performing a similar microextract and homogenate analysis, peptide and protein identifications were collected. There were much greater variations between identifications within the microextract regions, both at the peptide and protein level (Figure 3.4). This is supported by previous reports highlighting the very heterogeneous nature of molecules within these tumors.<sup>94</sup> A similar trend was observed for the microextract and homogenate comparison as was seen in the rat brain sample. Table 3.2 lists the identified proteins unique to the microextract analysis. Overall, the number of protein identifications was lower for the human ccRCC sample compared to the rat brain, most likely due to the fibrotic nature of the tumor. This was highlighted in the homogenization process, where extensive homogenization did not completely solubilize the tissue.

**Figure 3.4.** LC-MS/MS analysis of resected human ccRCC tumor regions sampled by microextraction and tissue homogenization. Identifications were considered confident within Scaffold Proteome Viewing software when they had a 99.9% Protein Threshold, a 95% Peptide Threshold, and a minimum of 2 peptides.

**Table 3.2.** Protein identifications from resected human ccRCC tumor regions exclusively observed by microextraction analysis. Identifications were considered confident within Scaffold Proteome Viewing software when they had a 99.9% Protein Threshold, a 95% Peptide Threshold, and a minimum of 2 peptides.

When comparing to a homogenization strategy, the combined results of the microextracts provided roughly one third of the protein identifications. This was expected because there were many parts of the tissue that were not sampled by microextraction that would have contributed to the homogenate identifications. However, there were ~70 protein identifications made by the microextract workflow that were not observed in the homogenate (Tables 3.1 and 3.2). The sample complexity of a microextract is much less than that of an in-solution digest of a tissue homogenate. Therefore, it stands to reason that it is much less likely for analytes to be suppressed during the LC analysis. Data-dependent acquisitions rely on peak intensities and exclusion lists to sort through spectra in real time, and samples such as homogenates have much larger differences in analyte dynamic range. This is not to say that abundant peptides and proteins would not also be observed in microextract analyses, however by reducing the complexity of a sample can aid in observing species that may coelute with highly abundant species and otherwise go undetected.

With the high performance characteristics of the FTICR and Q Exactive, peptide identifications could be made using mass accuracy to link the data sets, in a similar manner as described in Chapter II. Peak lists were compared between the MALDI IMS data and the LC-based identification approaches. Identifications were made for peaks with less than 5 ppm mass errors relative to the peptide molecular weight. Figure 3.4 shows examples of ions that were identified using this strategy. To do a complete and thorough comparison, informatics and isotope modelling software would prove beneficial. As the molecular weight increases, the isotopic distribution shifts from the monoisotopic peak. For larger peptides, this means that the most abundant isotope, which provides the highest S/N ion image, would not match to the theoretical mass of the peptide in most databases. Incorporating mass tolerances and isotopic

information into comparisons would provide for more efficient searches and higher yields in terms of confident identifications.

**Figure 3.5** MALDI FTICR IMS of rat brain peptides identified by localized extraction methods. Identifications were made by localized microextractions and verified with tissue homogenization methods. All peptide identifications had mass errors of ~5 ppm or less.

## Conclusions

Peptide analysis by MALDI FTICR IMS have been improved by robust sample preparation methods, including incubation optimization and spatially localized extraction for identifications. The incorporation of methods previously used for protein analysis have also improved sensitivity from biological tissues, providing analyte-rich spectra. Small volumes of ammonium bicarbonate (50-100  $\mu$ L) in the incubation chamber yielded the least amount of observed analyte delocalization while still producing spectra rich in peptide signals. The microextraction method allowed for bottom-up proteomic data to be analyzed on Q Exactive while still maintaining a 1 mm spatial area from within the tissue sections. In fact, roughly 70 protein identifications in each case study were only observed from the microextract analysis compared to a traditional homogenization approach. The high mass resolution and mass accuracy of these two instruments were used to correlate IMS and proteomic data for both rat brain and human ccRCC tumor samples. By utilizing the microextraction method to identify analytes by LC-MS/MS, identifications of peptides were made without the need for bulk tissue homogenization. These data showed the capabilities of MALDI FTICR IMS to provide the molecular specificity needed to overcome the challenges associated with direct tissue analysis.

## CHAPTER IV

### ADVANCED HYDROGEL TECHNOLOGIES FOR ENHANCED ON-TISSUE PROTEIN DIGESTION AND IMPROVED SPATIAL LOCALIZATION

#### Introduction

Protein identification for IMS experiments has historically been performed by homogenizing pieces of tissue, performing protein fractionation and digestion, and then leveraging classical LC-MS/MS bottom-up proteomics methods.<sup>144, 145</sup> Protein peaks observed in the IMS experiment are then matched to those observed in the LC-MS/MS experiment.<sup>146</sup> In Chapter II, top-down proteomics was used to help match high mass accuracy MALDI protein imaging mass spectrometry data to LC-based identifications of intact proteins.<sup>84, 85</sup> While bulk tissue homogenization provides analyte-rich samples for downstream proteomics experiments, little to no spatial information is retained. This reduces the ability to confidently correlate protein signals from the IMS experiment to the protein identifications from the LC-MS/MS experiment.

One method that enables protein identification while still maintaining some level of spatial localization is laser capture microdissection (LCM), where sample regions are perforated with a laser and catapulted into a collection device for downstream analysis.<sup>53-55</sup> Depending on the focus of the laser and magnification power of the microscope, individual cells or cell types can be collected out of complex samples, such as tissue biopsies,<sup>147</sup> plants,<sup>148</sup> or even individual glomeruli.<sup>149</sup> Though ideal for targets smaller than a millimeter, LCM instrumentation can be cost-prohibitive, time-consuming, and require substrates compatible with the laser. Traditionally, large cell counts have been required to produce robust proteomics results.<sup>57</sup>

Within the last several years, several other extraction approaches have been developed to extract proteins from tissue sections while preserving localization. For example, liquid microextractions have proven successful for targeting distinct regions of tissue for a wide variety of analyte classes.<sup>58,59</sup> Approaches such as liquid extraction surface analysis (LESA) have the added benefit of automated sample extraction and processing<sup>60</sup>, and can be coupled directly to the mass spectrometer for either top-down or bottom-up analyses.<sup>62,150</sup> In these types of experiments, the spatial limitation of the extraction is typically dictated by the physical characteristics of the liquid-sample interface, such as droplet diameter, contact angle, and surface tension.<sup>151</sup> Though research is ongoing to reduce the size of this effective footprint, most current applications have extraction diameters on the millimeter scale.

An alternative approach to direct liquid extractions or capture-based methods is the incorporation of hydrogel technologies into proteomic workflows.<sup>64, 66</sup> These polymer gels act as both a delivery system of reagents, such as enzymes, directly to the tissue sample, and a tool for localized analyte extraction. This allows for digestion and extraction to occur within one incubation period. Different iterations of hydrogels have been used in several biological applications, including both fresh frozen<sup>64, 66, 152</sup> and formalin-fixed, paraffin-embedded<sup>65</sup> (FFPE) samples. Hydrogels can be advantageous because of the relatively low-cost of the materials used in their preparation, straightforward use, and ability to perform diverse types of experiments in different areas of the same tissue section. Previous approaches have used hydrogels with diameters between 1-2 mm,<sup>66, 152</sup> which is similar in size to the areas sampled by liquid extractions.

## Methodologies for Hydrogel Comparisons & Analysis

### *Tissue Preparation and In-Solution Digests*

Fresh frozen rat livers were used because of their relatively large size compared to other organs, and due to the moderate homogeneity in terms of cell type and structure. As in chapters II and III, samples were sectioned at 12  $\mu\text{m}$  and thaw-mounted onto microscope slides and dried in a desiccator for 30 minutes before washing with the Carnoy's solution protocol<sup>96</sup> to remove endogenous salts and lipids. For experiments utilizing discrete regions of tissue collected by biopsy punch for in-solution digests, tissues were cryosectioned in an identical manner as above. While the tissue section was still frozen in the cryostat, a 1.5 mm diameter biopsy punch was used to resect regions from the tissue, and the thin tissue punch was moved to an Eppendorf tube for in-solution digestion and analysis. For LCM collection, areas of washed tissue sections were collected in circular regions with diameters of 1.2 mm and 1.5 mm to equal the hydrogel and tissue punch diameters, respectively. Samples were collected into 20  $\mu\text{L}$  of 100 mM ammonium bicarbonate in the cap of a PCR tube to ensure that the sample remained in the cap and did not fall back onto the surface.

Both LCM and tissue punch samples underwent in-solution digests modified from previous reports.<sup>153</sup> Briefly, the samples were suspended in solutions consisting of 10  $\mu\text{L}$  TFE, 25  $\mu\text{L}$  0.1  $\mu\text{g}/\mu\text{L}$  trypsin, and a total of 65  $\mu\text{L}$  100 mM ammonium bicarbonate. Only 45  $\mu\text{L}$  of 100 mM ammonium bicarbonate was added to the LCM samples, as 20  $\mu\text{L}$  was already present from the collection process. Samples were incubated at 37°C for 14 hours, dried using a centrifugal vacuum concentrator and then reconstituted in 0.1% TFA. Extracts were desalted and purified using C<sub>18</sub> ZipTips and analytes were eluted into new low-retention microcentrifuge

tubes. Samples were dried down and reconstituted in 10  $\mu$ L 0.1% formic acid for LC-MS/MS analysis.

### *Hydrogel Workflow*

Fabrication: Gels were cast as previously described by Nicklay et al.,<sup>66</sup> with modifications made to the manufacturer's gel formulation guidelines in order to achieve 7.5%, 10%, 12%, 15%, and 18% polyacrylamide gels. Briefly, 30% acrylamide/bis-acrylamide, 1.5M Tris (pH 8.7), and ddH<sub>2</sub>O were combined in a vacuum flask and degassed under vacuum for 30 minutes with constant stirring. The solution was poured into a 60 x 15 mm polystyrene Petri dish and 10% ammonium persulfate and TEMED were added. The Petri dish was covered and gently swirled to ensure even mixing, then left to polymerize overnight. The resulting polymer had a measured thickness of ~1.7 mm. Biopsy punches of varying sizes (4, 3, 2, 1.5, 1, 0.75, and 0.5 mm) were used to fabricate hydrogels of different diameters. Individual hydrogels were collected in Eppendorf tubes and dried in a centrifugal vacuum concentrator for long-term storage at -80°C.

Placement and incubation: Tissue sections were brought to room temperature in a desiccator prior to hydrogel placement. Porcine trypsin was dissolved in 100 mM ammonium bicarbonate (pH 7.8) to produce concentrations of 0.01, 0.025, 0.1 or 1  $\mu$ g/ $\mu$ L. Hydrogels were reswelled for 15 min in these trypsin solutions, except for the tissue blanks, which consisted of 7.5% and 18% polyacrylamide hydrogels swelled with 100 mM ammonium bicarbonate alone prior to placement. Hydrogels were placed on the tissue sections, ensuring minimal excess liquid and good contact with the tissue surface. Each experimental condition was repeated a minimum of three times to allow for statistical analysis. A subset of the trypsin-swelled 7.5% and 18% polyacrylamide hydrogels were placed directly on the microscope slide surface with no tissue

present to serve as trypsin blanks. All samples were placed in an incubation chamber<sup>39, 96</sup> containing 1 mL of 100 mM ammonium bicarbonate, sealed with lab tape, and incubated at 37°C for 14 hrs. Samples were removed from the incubation chamber and hydrogels were placed in Eppendorf tubes for analyte extraction.

Extraction from the hydrogels: Analytes were extracted using a modified version of a previous hydrogel extraction protocol,<sup>66, 152</sup> utilizing increasing organic solutions (50%, 60%, 80%, and 3x 95% ACN containing 5% formic acid) alternating with 100 mM ammonium bicarbonate. The organic solutions aided in solubilizing the extracted peptides as well as dehydrating the gels. Conversely, the ammonium bicarbonate rehydrated the gels, reswelling them in between organic steps. Each step had a 5 min incubation followed by centrifugation for 5 min at 6,610xg. The supernatants from each step were pooled into siliconized low-retention microcentrifuge tubes. Once the extraction process was completed, the combined supernatants were dried down using a centrifugal vacuum concentrator and reconstituted in 0.1% TFA. Extracts were desalted and purified using C<sub>18</sub> ZipTips and analytes were eluted into new low-retention microcentrifuge tubes. The samples were again dried and reconstituted in 10 µL 0.1% formic acid for LC-MS/MS analysis. For instrument reproducibility experiments, three hydrogel extracts (post ZipTip purification) were combined into one tube, dried down, and then reconstituted in 30 µL 0.1% formic acid for LC-MS/MS analysis.

#### *LC-Coupled Tandem Mass Spectrometry (HCD)*

Bottom-up analysis was performed using an Orbitrap Fusion Tribrid Mass Spectrometer (Thermo Scientific) coupled to an Easy-nLC 1000 (Thermo Fisher Scientific) ultrahigh pressure liquid chromatography (UHPLC) system. Peptides separation was achieved using a 75 µm inner

diameter, 25 cm long PepMap RSLC C18 column (2  $\mu\text{m}$ , 100  $\text{\AA}$ , Acclaim) with a flow rate of 300 nL/min (mobile phase solvent A: 0.1% formic acid, 99.9% water; mobile phase solvent B: 0.1% formic acid, 99.9% acetonitrile). The LC gradient ran from 2-20%B in 100 min, 20-32%B in 20 min, 32-95%B in 1 min, 95%B for 4 min, 95-2%B for 2 min, and the column equilibrated at 2%B for 3 min. Following gradient-elution, peptides were ionized using nanoelectrospray ionization on a Nanospray Flex ion source (Thermo Fisher Scientific). The Orbitrap mass spectrometer was operated in a 3 second top speed data-dependent acquisition (DDA) mode. Fourier transform mass spectra (FTMS) were acquired at 120,000 resolution with an automated gain control (AGC) target of 200,000 and a maximum injection time of 50 ms. Precursor ions were filtered according to monoisotopic precursor assignment and charge state ( $9 > z > 1$  required). Previously interrogated precursor ions were omitted using a dynamic exclusion window ( $30 \text{ s} \pm 10 \text{ ppm}$ ). Precursor ions for MS/MS analysis were isolated using a 1.5  $m/z$  quadrupole mass filter isolation window and were fragmented with higher energy dissociation (HCD) using a normalized collision energy of 35%. Ion trap MS/MS spectra were collected using an AGC target of 1,000 and maximum injection time of 40 ms.

### *Data Analysis*

Raw data files were converted to .mgf format by msConvert (ProteoWizard). Files were then searched against the Uniprot *Rattus norvegicus* proteome and processed using X! Tandem's GPM Cyclone web interface using the predefined Orbitrap (20 ppm) method. Methionine oxidations were included as potential modifications. Confident protein identifications were made with a 2 unique peptide threshold as well as an FDR of less than 2%. Statistical tests were subsequently performed on the data using Graphpad Prism software, including one-way

ANOVAs and Tukey's multiple comparison tests to assess significance at  $\alpha=0.05$  (95% confidence).

**Figure 4.1:** General hydrogel fabrication, usage, and extraction workflow. Hydrogels were fabricated in advance in large quantities and stored in cold temperatures to ensure minimal contamination or bacterial growth.

### Optimizing Trypsin Concentration for Efficient On-Tissue Digestion

Previous reports have used 1  $\mu\text{g}/\mu\text{L}$  trypsin concentrations in hydrogels for successful digestion for proteomics experiments.<sup>66, 154</sup> This moderately high concentration of enzyme can be cost-prohibitive when performing many hydrogel experiments using proteomics-grade trypsin. Additionally, even with reductive methylation<sup>155</sup> and TPCK treatment<sup>156</sup> to reduce autolysis and non-specific cleavages, trypsin autolytic peaks are still present in concentration-dependent quantities as seen in Table 4.1 and Figure 4.2. These values encompass all tryptic peptide identifications, including multiple charge states of the same peptide, modified and unmodified forms of individual peptides, as well as peptides containing missed cleavages. Statistical

comparisons were performed to highlight the significant concentration dependence for autolytic peaks (Tables 4.2 & 4.3). Loading of the hydrogels with trypsin concentrations which maximize digestion yet minimize enzyme consumption and interference is important to the broad-scale adoption of this methodology.

<b>Trypsin Autolytic Peptides from Hydrogels with Different Trypsin Concentrations</b>

0.01 vs 1	-1.80E+02	34.410	Yes	***	-204.1 to -156.6
0.025 vs 0.1	-3.23E+01	6.169	Yes	*	-56.07 to -8.595
0.025 vs 1	-1.80E+02	34.410	Yes	***	-204.1 to -156.6
0.1 vs 1	-1.48E+02	28.240	Yes	***	-171.7 to -124.3

**Table 4.3.** Tukey's multiple comparison test for numbers of identified trypsin autolytic peptides from hydrogels with different trypsin concentrations at the 0.05 significance level. ns: not significant; \*:  $p \leq 0.05$ ; \*\*:  $p \leq 0.01$ ; \*\*\*:  $p \leq 0.001$

**Figure 4.2.** Average numbers of identified trypsin autolytic peptides from hydrogels with different trypsin concentrations.  $n=3$  for each concentration of trypsin. \*:  $p \leq 0.05$ ; \*\*:  $p \leq 0.01$ ; \*\*\*:  $p \leq 0.001$

When comparing the number of non-trypsin protein identifications and variances between the concentrations of trypsin (Tables 4.4 and 4.5), there are observed differences in the total number of protein identifications. However, they are not statistically significant for hydrogels containing 0.025, 0.1, and 1  $\mu\text{g}/\mu\text{L}$  trypsin ( $1107 \pm 10$ ,  $1114 \pm 8$ , and  $1075 \pm 14$  protein identifications, respectively) as seen in Table 4.6 and Figure 4.3. There was a significant decline in the number of identified proteins when the concentration was decreased to 0.01  $\mu\text{g}/\mu\text{L}$ , with a total of  $892 \pm 84$  protein identifications. This is most likely due to a non-optimal trypsin:analyte ratio, with decreased enzymatic efficiency experienced with both too much and too little enzyme.<sup>157</sup> Trypsin concentrations that are too low relative to the analyte concentration will result in incomplete digestion or missed cleavages, while too high of a ratio of trypsin could lead to non-specific digestion.<sup>132</sup> Hydrogels containing 0.1  $\mu\text{g}/\mu\text{L}$  trypsin had the highest number of identified proteins with the lowest variances, and were used for all subsequent experiments.

### Increasing Polyacrylamide Percentages for Improved Hydrogel Rigidity

The percentage of polyacrylamide in a polymer solution can dictate many physical attributes, such as porosity, rigidity, and elasticity.<sup>158</sup> Of particular interest is how these factors affect the production and functionality of hydrogels in a proteomics workflow. Previous reports of hydrogel fabrications have utilized 7.5% polyacrylamide (37.5:1 monomer:crosslinker) to fabricate hydrogels, due mainly to its prevalence in the field of proteomic separations. Increasing

this percentage of polyacrylamide results in more rigid polymers, which are, in turn, more amenable to perforating individual hydrogels using punch biopsies. However, at higher percentages of polyacrylamide, analyte mobility may be hindered, preventing optimal extraction of proteins and peptides into the gel.<sup>159</sup>

Altering the percentage of polyacrylamide within the hydrogels according to Table 4.7 led to no statistical differences between the resulting numbers of protein identifications (Tables 4.8-4.10). All five percentages had approximately 1,200 confident identifications within the respective standard deviations, as seen in Figure 4.4.

<i>% Acrylamide</i>	<b>7.5%</b>	<b>10%</b>	<b>12%</b>	<b>15%</b>	<b>18%</b>
30% Acrylamide/Bis (mL)	1.25	1.67	2.00	2.50	3.00
1.5 M Tris, pH 8.7 (mL)	1.25	1.25	1.25	1.25	1.25
ddH <sub>2</sub> O (mL)	2.48	2.06	1.73	1.23	0.73

**Table 4.10.** Tukey's multiple comparison test for differences in numbers of protein identifications from hydrogels with different polyacrylamide percentages at the 0.05 significance level. ns: not significant; \*:  $p \leq 0.05$ ; \*\*:  $p \leq 0.01$ ; \*\*\*:  $p \leq 0.001$

**Figure 4.4.** Average numbers of protein identifications from hydrogels with different polyacrylamide percentages. Each hydrogel was swelled with 0.1  $\mu\text{g}/\mu\text{L}$  trypsin prior to placement.  $n \geq 3$  for each concentration. No statistically significant differences were observed between the percentages of polyacrylamide hydrogels.

The molecular weight distributions of identified proteins were consistent for both the 7.5 and 18% polyacrylamide, with no observable mass bias as the percentage of polyacrylamide was increased (Table 4.11 and Figure 4.5). This supports the hypothesis that even though the porosity of the hydrogel decreases with increasing percentages of polyacrylamide, the resulting analyte extraction of peptides is unhindered. These distributions closely mirror that of the rat proteome, confirming relatively even proteomic sampling from the tissue. Since the 18% polyacrylamide hydrogels yielded similar numbers of protein identifications when compared to the traditional 7.5% polyacrylamide hydrogels, the 18% gels were chosen to fabricate all subsequent hydrogels because of the ability to more easily and reproducibly prepare the hydrogels.

**Table 4.11.** Molecular weight bins of protein identifications from 7.5% and 18% polyacrylamide hydrogels and the Uniprot Rat Proteome. Both 7.5% and 18% polyacrylamide hydrogels were used to ensure there was no bias among polyacrylamide percentages.

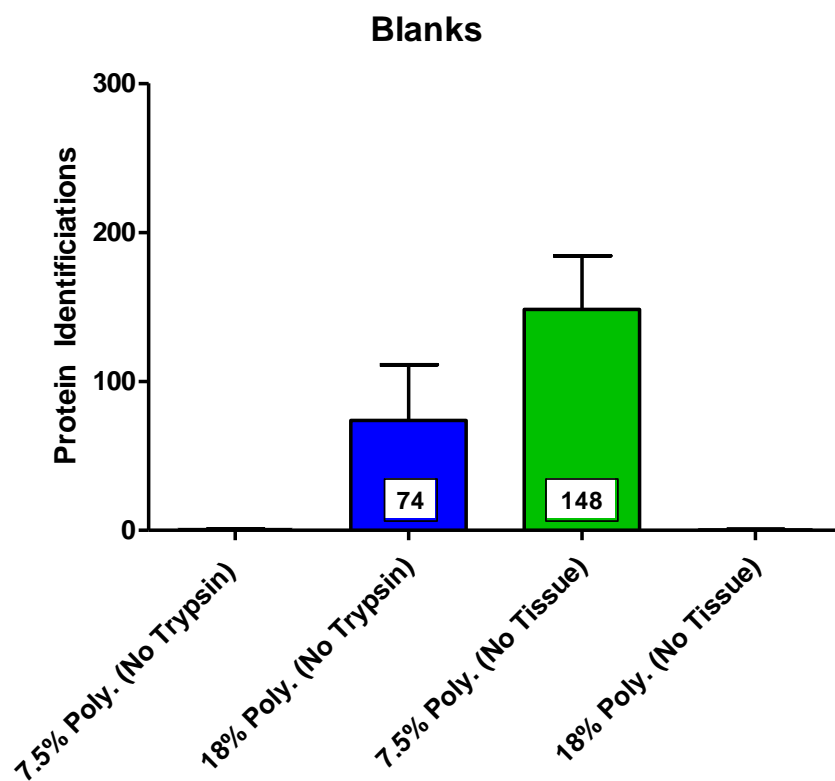

**Figure 4.5.** Molecular weight distributions of protein identifications from 7.5% and 18% polyacrylamide hydrogels and the reviewed protein identifications in the Uniprot rat protein database. Masses of identified proteins were binned for the 7.5% (red) and 18% (blue) polyacrylamide hydrogels (left axis), as well as the UniProt rat proteome (yellow – right axis). n=5 for both of the hydrogel conditions.

In order to ensure that the variability in protein identifications were not due to background interferences, a series of controls were investigated (Table 4.12). Five replicates of 7.5% and 18% polyacrylamide hydrogels containing no trypsin (tissue blanks) were examined to assess endogenous peptide extraction from tissue. No confident identifications were consistently made for the 7.5% polyacrylamide hydrogels, while the 18% polyacrylamide hydrogels produced statistically insignificant numbers of identifications ( $74 \pm 84$  confident proteins). Additionally, hydrogels swelled with trypsin and placed directly onto the microscope slide were used to gauge sample preparation contamination, such as analyte delocalization caused by tissue washes. The 7.5% polyacrylamide hydrogels did produce a number of protein identifications, though largely inconsistent. Conversely, the 18% polyacrylamide hydrogels resulted in negligible identifications. No over-arching trends were observed for either set of blanks, supporting the hypothesis that variations in protein identifications were due to the experimental conditions rather than any background interferences.

Protein Identifications from Control (Blank) Hydrogels				
<i>Control (Blank)</i>	<i>n</i>	<i>Average</i>	<i>Variance</i>	<i>Std Deviation</i>
7.5% Polyacrylamide - No Tissue	3	148	3884	62
18% Polyacrylamide - No Tissue	3	0	0	1
7.5% Polyacrylamide - No Trypsin	5	0	0.3	1
18% Polyacrylamide - No Trypsin	5	74	6986.7	84

**Table 4.12.** Average numbers of protein identifications from control (blank) hydrogels. Both 7.5% and 18% polyacrylamide hydrogels were used to ensure there was no bias among polyacrylamide percentages. Tissue blanks were hydrogels swelled in 100 mM ammonium bicarbonate and incubated on tissue (no trypsin). Trypsin blanks were hydrogels swelled in trypsin solutions, but placed directly onto the microscope slide (no tissue).

**Figure 4.6.** Average numbers of protein identifications from control (blank) hydrogels. Both 7.5% and 18% polyacrylamide hydrogels were used to ensure there was no bias among polyacrylamide percentages. Tissue blanks were hydrogels swelled in 100 mM ammonium bicarbonate and incubated on tissue (no trypsin). Trypsin blanks were hydrogels swelled in 0.1  $\mu\text{g}/\mu\text{L}$  trypsin solutions, but placed directly onto the microscope slide (no tissue).  $n=5$  for tissue blanks (no trypsin) and  $n=3$  for trypsin blanks (no tissue).

Instrument reproducibility was also assessed to confirm minimal instrument bias between analytical runs. Any discrepancies in liquid chromatographic separation or mass spectrometric acquisition would be observed from technical replicates of a single sample. The number of protein identifications from this triplicate analysis was highly reproducible, resulting in an average of 1,072 confident identifications with a standard deviation of only five proteins, as seen in Table 4.13 and Figure 4.7. When comparing the actual protein identifications, there was a great deal of overlap between the replicates, again highlighting the reproducibility of the analysis (Figure 4.8). A total of 860 proteins were identified in the three replicate runs, which accounts for 63.9% of all protein identifications. An additional 149 proteins were identified in any two of the three runs, or 11% of the protein identifications. This meant that only 25% of the identifications were only observed in a single replicate run.

<b>Protein Identifications from Technical Replicate Runs of a Hydrogel Extract</b>					
<i>Replicate 1</i>	<i>Replicate 2</i>	<i>Replicate 3</i>	<i>Average</i>	<i>Variance</i>	<i>Std Deviation</i>
1071	1077	1067	1072	25	5

**Table 4.13.** Average number of protein identifications from the analysis of a technical replicate experiment repeated three times. Three hydrogel extracts (18% polyacrylamide, 3 mm biopsy punch) were pooled together and diluted three-fold to achieve a total concentration comparable to a single hydrogel experiment. This solution was analyzed three times and the protein identification numbers were compared. The methods appear to be highly reproducible, with an average of  $1072 \pm 5$  identified proteins.

**Figure 4.7.** Average number of protein identifications from the analysis of a technical replicate experiment repeated three times. Reproducibility of the HPLC-MS/MS methods and instrumentation were assessed. Three hydrogel extracts (18% polyacrylamide, 3 mm biopsy punch) were pooled together and diluted three-fold to achieve a total concentration comparable to a single hydrogel experiment. This solution was analyzed three times and the protein identification numbers were compared. The methods appear to be highly reproducible, with an average of  $1072 \pm 5$  identified proteins.

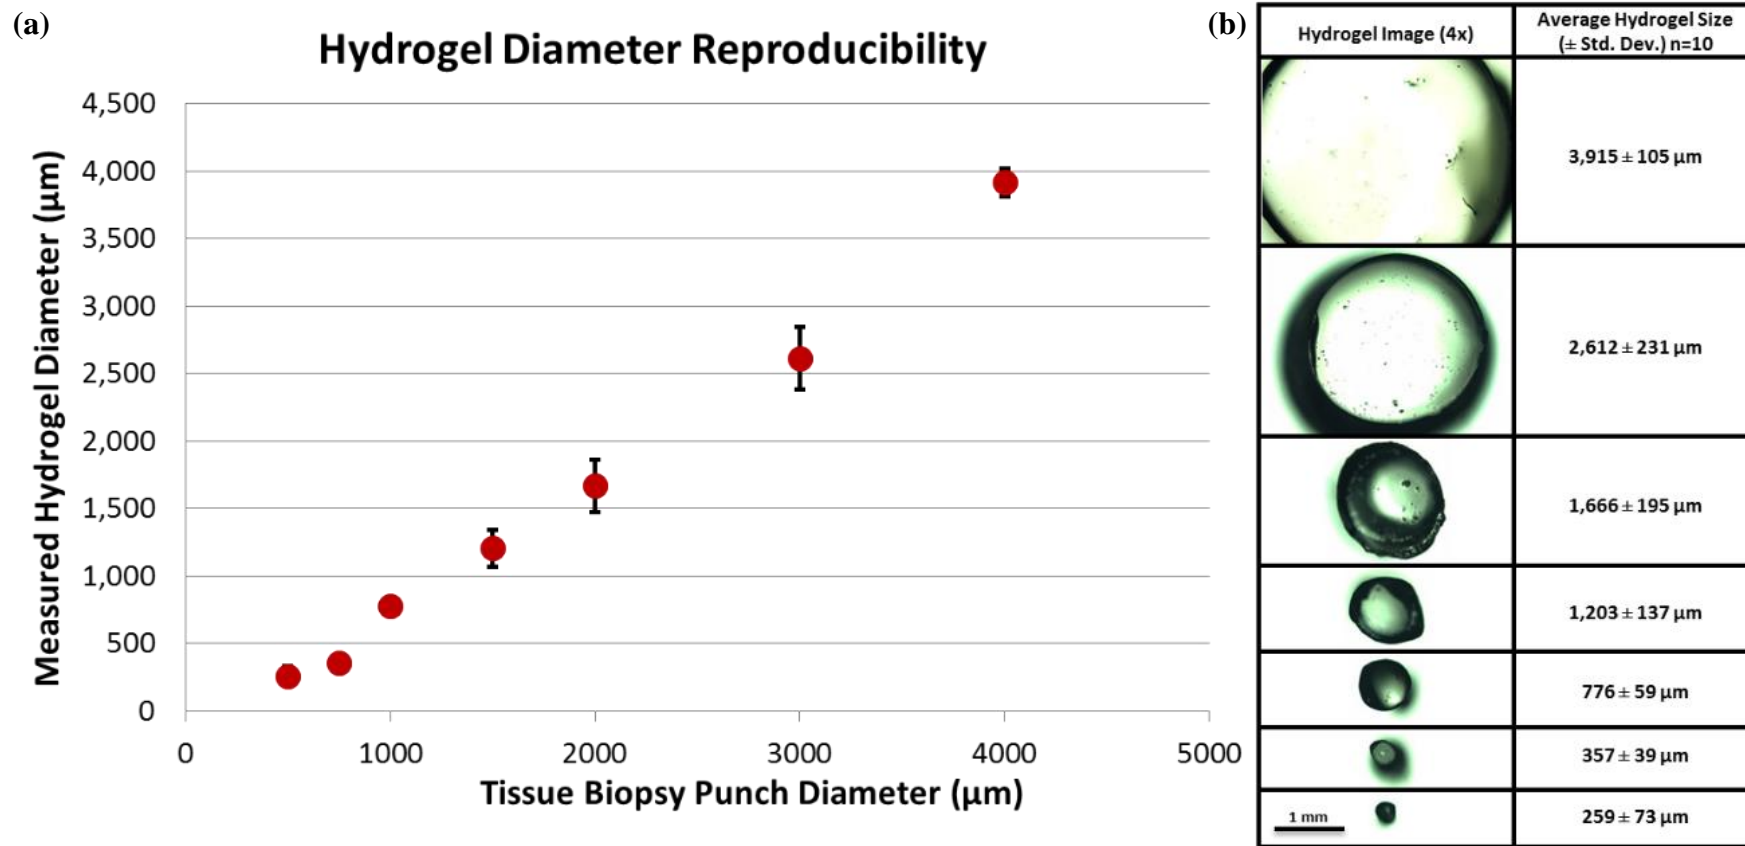

**Figure 4.8.** Venn diagram of protein identifications from the three hydrogel replicates. Over 60% of the identified proteins were found in all three hydrogels (860 protein identifications), and this number increases to ~75% if proteins identified in any two out of the three runs are considered (1,009 protein identifications). Only ~8% of the identifications from each replicate run were unique and not found in the other runs.

### Fabricating Smaller Hydrogels for More Localized Analyte Extraction

Ten hydrogels were fabricated using 4, 3, 2, 1.5, 1, 0.75, and 0.5 mm biopsy punches, and the resulting hydrogel diameters were measured using a microscope (Table 4.14 and Figure 4.9). Although the hydrogels did not have the same diameter as the biopsy punches used to fabricate them, the standard deviations were  $<250 \mu\text{m}$  for each measurement group. The discrepancy between the punch diameter and the hydrogel diameter can be attributed to the ductile properties of the gel, causing distortion during the perforation process. This was only minimally observed at larger dimensions, with hydrogel diameters measuring  $>75\%$  of the punch diameter for the 4, 3, 2, 1.5, and 1 mm biopsy punches. However, utilizing the 0.75 and 0.5 mm biopsy punches resulted in reproducible hydrogel diameters of 357 and 259  $\mu\text{m}$  respectively, which is  $\sim 50\%$  of the biopsy punch diameters.

Diameter Measurements of Hydrogels Fabricated with Different Biopsy Punch Diameters							
Punch Biopsy Diameter (mm)	4	3	2	1.5	1	0.75	0.5

**Table 4.14.** Average diameter measurements of hydrogels fabricated with different diameters biopsy punches. Ten measurements were recorded for each biopsy punch diameter.

**Figure 4.9.** Measured diameters of 18% polyacrylamide hydrogels fabricated with different diameter biopsy punches. (a) A graph of the biopsy punch diameters vs. measured hydrogel diameters. n=10 for each measurement and the standard deviation is plotted. (b) Optical images of each hydrogel size as well as the measured diameters and standard deviation for each measurement. Scale bar: 1 mm.

In order to test the utility of these smaller diameter hydrogels, hydrogels fabricated from biopsy punches with diameters of 2, 1.5, 1, 0.75, and 0.5 mm were investigated. As the diameter of the biopsy punch decreased, ultimately decreasing the fabricated hydrogel diameter, the number of protein identifications showed a similar trend (Table 4.15-4.17). The 2 mm biopsy punch hydrogels resulted in 1,052 identifications with a standard deviation of only 7 identifications. The standard deviations for the 1.5, 1, 0.75, and 0.5 mm biopsy punches were higher, with standard deviations of 77, 56, 78, and 56 identifications, respectively. However, even the smallest diameter hydrogels still provided 671 confident protein identifications. (Figure 4.10a). To ensure the hydrogels were only sampling from the tissue directly beneath them, the tissue sections were H&E stained post-hydrogel removal. Figure 4.10b shows the result of a 259  $\mu\text{m}$  diameter hydrogel digestion on a rat liver section with the surrounding tissue largely undisturbed from the digestion and extraction process. The vast majority of the signal is therefore derived only from cells being sampled under the hydrogels.

<b>Protein Identifications from Hydrogels Fabricated with Different Biopsy Punch Diameters</b>				
<i>Biopsy Punch Diameter (mm)</i>	<i>Count</i>	<i>Average</i>	<i>Variance</i>	<i>Std Deviation</i>
0.5	3	671	3163	56

**Figure 4.10.** Evaluating the utility and effectiveness of smaller diameter hydrogels in a proteomics workflow. (a) Average number of protein identifications detected from 18% polyacrylamide hydrogels fabricated with different diameter biopsy punches all containing 0.1  $\mu$ g/ $\mu$ L trypsin.  $n \geq 3$  for each size. (b) H&E-stained tissue section after a 260  $\mu$ m diameter hydrogel (0.5 mm biopsy punch) was removed. The outline of the hydrogel is represented by the yellow dotted line. Scale bar: 100  $\mu$ m.

An approximate calculation was performed to assess the number of cells beneath a 259  $\mu\text{m}$  diameter hydrogel, defined by the ratio of the surface area of the hydrogel to the surface area of a eukaryotic cell (conservatively estimated to be 10  $\mu\text{m}$  in diameter<sup>160</sup>):

$$\pi r^2 = A$$

$$\pi \left( \frac{259 \mu\text{m}}{2} \right)^2 = 5.27 \times 10^4 \mu\text{m}^2$$

$$\pi r^2 = A$$

$$\pi \left( \frac{10 \mu\text{m}}{2} \right)^2 = 78.5 \mu\text{m}^2$$

$$\frac{5.27 \times 10^4 \mu\text{m}^2 \text{ hydrogel area}}{78.5 \mu\text{m}^2 \text{ cell area}} = 671 \text{ cells}$$

Though this calculation makes assumptions about the circular shape of both hydrogels and cells, the approximation provides general context for the protein yields from such small sample areas. Comparatively, LCM-based protocols traditionally recommend cell counts at least an order of magnitude higher for robust protein-based analyses.<sup>57</sup>

### **Comparison of Sample Collection Methods**

A direct comparison of hydrogel-mediated protein identifications to both LCM and tissue homogenization methodologies was performed to validate the hydrogel approaches against existing methods. A biopsy punch with a diameter of 1.5 mm was used to fabricate hydrogels with a resulting diameter of ~1.2 mm. The same diameter biopsy punch was used to perforate 12  $\mu\text{m}$ -thick tissue sections and place the 1.5 mm tissue punches into individual Eppendorf tubes. To account for the discrepancy between the diameters of the hydrogel and the tissue punches,

LCM was used to collect circular regions at diameters of both 1.2 and 1.5 mm. The hydrogels were incubated on-tissue, while the LCM and tissue punch digestions were incubated for the same amount of time in-solution.

<b>Protein Identifications from Different Sample Collection Methods</b>				
<i>Sample Collection Methods</i>	<i>Count</i>	<i>Average</i>	<i>Variance</i>	<i>Std Deviation</i>

1.5mm LCM vs 1.5mm Tissue Punch	-1.26E+02	4.249	No	ns	-259.6 to 8.271
1.2mm Hydrogel vs 1.5mm Tissue Punch	1.27E+01	0.428	No	ns	-121.3 to 146.6

**Table 4.20.** Tukey's multiple comparison test for differences in numbers of protein identifications from different sample collection methods at the 0.05 significance level. ns: not significant; \*:  $p \leq 0.05$ ; \*\*:  $p \leq 0.01$ ; \*\*\*:  $p \leq 0.001$

**Figure 4.11.** Average numbers of protein identifications from different sample collection methods. Circular tissue regions with diameters of 1.2 and 1.5 mm were collected by LCM. A 1.5 mm biopsy punch was used to collect circular regions of tissue and perform in-solution digests in parallel to LCM experiments. Hydrogels with diameters of 1.2 mm were placed on serial tissue sections and incubated for the same period of time as the in-solution digests. n=3 for each method. ns: not significant; \*:  $p \leq 0.05$ ; \*\*:  $p \leq 0.01$ ; \*\*\*:  $p \leq 0.001$

Compared to the tissue punch method, which requires separate collection and incubation steps, the hydrogel digestion/extraction process yielded statistically similar results as seen in Tables 4.18-4.20 and Figure 4.11 ( $889 \pm 18$  and  $902 \pm 77$  protein identifications, respectively). Though manual manipulation of hydrogels may prove challenging with smaller diameter gels, a tissue punch of the same diameter would inherently prove to be more difficult.

The 1.2 mm hydrogel outperformed both the 1.2 mm and 1.5 mm LCM experiments, which had  $708 \pm 17$  and  $764 \pm 64$  identifications. The decreased number of protein identifications from the LCM process relative to the other methods is most likely due to sample loss during the catapulting process of the sample into the collection apparatus. Though robust, this transfer method is not 100% efficient, as seen by particulates falling back down onto the sample between laser pulses. This, compounded by the high cost of equipment, potentially long collection times, and separate digestion steps, highlights an advantage of the hydrogel technologies.

### **Differential Proteomic Analysis of Rat Cerebellum Substructures**

The need for spatially-directed proteomic analyses is particularly useful for spatially heterogeneous tissue samples with many different cell types. These can include organ substructures,<sup>31, 161</sup> the interface between a host and infectious agents,<sup>146, 162</sup> or the infiltration of diseased tissue, such as a cancerous growth, into surrounding healthy tissue.<sup>71, 94, 163, 164</sup> The rat cerebellum is a simple example that has many distinct layers comprising the tissue, including the white matter, granule layer, and molecular layer.

Hydrogels were fabricated with a 1 mm diameter biopsy punch and placed on either the white matter or the molecular layer, designated by the circles in Figure 4.12a. These hydrogels

were placed less than 1 mm away from each other to highlight the ability of hydrogel technologies to perform independent experiments in close spatial proximity. LC-MS/MS experiments showed that while there was a great deal of overlap between the identified proteins from each region, the white matter had 272 unique proteins and the molecular layer had 174 unique proteins (Figure 4.12b). The top ten unique protein identifications based on X! Tandem rankings for each hydrogel are listed in Table 4.21.

	<b>Accession</b>	<b>Description</b>
<b>White Matter</b>	TBA1_RAT	Tubulin alpha-1A chain
	MAG_RAT	Myelin-associated glycoprotein
	NOTC3_RAT	Neurogenic locus notch homolog protein 3
	MOG_RAT	Myelin-oligodendrocyte glycoprotein
	HNRPD_RAT	Heterogeneous nuclear ribonucleoprotein D0
	CXA1_RAT	Gap junction alpha-1 protein
	H2A4_RAT	Histone H2A type 4
	PIMT_RAT	Protein-L-isoaspartate(D-aspartate) O-methyltransferase
	CDC5L_RAT	Cell division cycle 5-like protein
	NOVA1_RAT	RNA-binding protein Nova-1
<b>Molecular Layer</b>	TBA2_RAT	Tubulin alpha-1B chain
	CAC1G_RAT	Voltage-dependent T-type calcium channel subunit alpha-1G
	MYH11_RAT	Myosin-11
	NDKB_RAT	Nucleoside diphosphate kinase B
	UN13A_RAT	Protein unc-13 homolog A
	HD_RAT	Huntingtin
	NRX2A_RAT	Neurexin-2
	THIKA_RAT	3-ketoacyl-CoA thiolase A, peroxisomal
	ITB1_RAT	Integrin beta-1
	CO3A1_RAT	Collagen alpha-1(III) chain

**Table 4.21.** The 10 highest-ranked hydrogel-mediated protein identifications unique to the white matter or molecular layer of the rat cerebellum.

**Figure 4.12.** Differential proteomic analysis of rat cerebellum substructures. (a) H&E section of 12  $\mu\text{m}$  thick rat cerebellum tissue after two hydrogels with diameters of  $\sim 777 \mu\text{m}$  were placed on either the white matter or molecular layer. The regions have been denoted by the circles overlaid on the H&E. Scale bar: 2 mm. (b) Venn diagram of protein identifications from the two cerebellum regions. The diagram is color-coded to match the circles shown in (a).

These identifications within the rat cerebellum are supported by previous literature reports.<sup>165</sup> For example, myelin-associated glycoprotein and myelin-oligodendrocyte glycoprotein are highly expressed in white matter regions within the central nervous system and are found to diminish with age, leading to disorders such as Alzheimer's and Parkinson's disease.<sup>166-168</sup> Conversely, neurexin-2 and voltage-dependent T-type calcium channel subunit alpha-1G, found in the molecular layer, mediate neuronal signaling and electrophysiological activity, respectively.<sup>169, 170</sup> A complete list of identified proteins can be found in Appendix A-C. One potential explanation for the high overlap is due to the granule layer, seen as dark purple in the H&E stained section, and the Purkinje layer, which is a one-cell thick layer between the white matter and the granule layer. Both hydrogels were tangential to these layers, with small portions present within the digestion/extraction regions underneath the hydrogels. It stands to reason that proteins are relatively homogeneous within specific layers, so both hydrogels would extract similar analytes from these interfering regions of tissue.

## Conclusions

The current methodologies for hydrogel-mediated analysis have been improved to allow for more efficient analyte:trypsin ratios and the use of more rigid polymers. Trypsin concentrations were reduced 10-fold while still maintaining the detection of over 1,000 proteins. The use of 18% polyacrylamide to cast hydrogels led to more reproducible hydrogel diameters as well as the ability to fabricate smaller hydrogels down to 260  $\mu\text{m}$ . Even these narrow hydrogels provided robust proteomics data, with over 670 proteins confidently identified. The tissue adjacent to these small hydrogels does not appear to be altered in any way, as seen by H&E

staining post-hydrogel removal. This means that the hydrogels are truly sampling the tissue directly below them, not delocalizing into the surrounding areas.

On-tissue hydrogel digestion and extractions performed statistically better than in-solution digests from LCM and were comparable to tissue punch workflows, supporting this methodology as an easy to use and cost-effective alternative for many biological studies. When applying the newly optimized hydrogels to a rat cerebellum tissue, close to 1,000 proteins were identified from the white matter and molecular layer. Though there was a great deal of overlap between the identified proteins between the two substructures, 272 identifications were unique to the white matter and 174 identifications were unique to the molecular layer. Upon closer inspection, the top-ranked proteins that were unique to each region made biological sense, and were supported by previous literature reports.

## CHAPTER V

### CONCLUSIONS & PERSPECTIVES

#### **MALDI FTICR IMS of Intact Proteins: Using Mass Accuracy to Link Protein Images with Proteomics Data**

Next-generation MALDI imaging platforms can provide unprecedented performance in terms of mass resolution for spatial proteomics experiments. The advantages of performing imaging experiments of intact proteins using MALDI FTICR IMS have been shown with vastly different tissue types. In the analysis of rat brain tissue, the ability to detect proteins with good sensitivity up to  $m/z \sim 17,000$  and proteins as large as  $\sim 20$  kDa was achieved. This is an  $m/z$  increase of almost 5,000 over previously reported results. IMS of rat brain tissue and clear cell renal cell carcinoma tissue from a human patient using MALDI FTICR IMS produced ion images with high mass resolution ( $\sim 75,000$  at  $m/z$  5,000) and accuracy ( $< 5$  ppm). The analysis of ccRCC tissue elucidated proteins that were observed to be at greater abundance in the healthy tissue regions of the tissue (HH4-AC/2Me,  $[M+2H]^{2+}$ , -4.4 ppm), within the tumor (Thy $\beta$ 10-AC,  $[M+H]^{1+}$ , 3.1 ppm), and also localized to areas of increased vascularization around the tumor (HBB,  $[M+2H]^{2+}$ , 4.7 ppm). These data showed the capabilities of MALDI FTICR IMS to provide the molecular specificity needed to overcome the challenges associated with direct tissue analysis. Improving spectral performance criteria such as mass resolving power and accuracy are critical for next-generation molecular imaging experiments. Specifically, direct tissue analysis provides unique challenges associated with overcoming bimolecular complexity and protein identification. For example, only 15 confident IMS identifications were made using this approach, due in large part to differences in observed peaks between the MALDI IMS and LC-

ESI MS/MS experiments. Although many more peaks were observed in each data set, the focus of this study was on the ions observed in both sets. Continued work must focus on addressing the inherent differences between these two ionization techniques in order to increase the number of identifications.

## **Spatially-Targeted Extractions to Improve Peptide Identifications from MALDI FTICR**

### **IMS Experiments**

MALDI FTICR IMS can be an extremely useful tool for not only protein imaging, but peptide imaging as well. High mass resolution and mass accuracy aids in differentiating near isobaric peptide signals, many of which have overlapping isotopic envelopes. Though matrices such as CHCA have been used previously for peptide IMS experiments, the incorporation of a DHA method has greatly improved the signal intensities and peak abundances. This volatile matrix can rapidly sublime off of samples in high vacuum sources, such as those found on TOFs, but the reduced pressure source of the FTICR makes it perfectly amenable to DHA imaging. Sample preparation optimization also included the investigation of incubation conditions to ensure sufficient digestion while still minimizing delocalization. Volumes of ammonium bicarbonate were reduced to 50-100  $\mu\text{L}$  for over-night digests, but still maintained robust peptide signals detected on the FTICR.

Integrating spatially-driven proteomic identification approaches, such as microextractions, into the imaging workflow provided rich peptide and protein datasets. This method is favored over homogenization because it maintains spatial information while remaining relatively easy to perform. Additionally, approximately 70 proteins were identified from the microextract that were not observed in the homogenate analysis. Microextracts have been used to

extract proteins prior to in-solution digestion, but extracting peptides from a tissue that has undergone the same *in situ* digestion as is used for imaging mass spectrometry experiments increases the chance that the peptides will be observed in both datasets. It reduces a major variable that could interfere with the confident identifications of peptides and proteins from tissue.

### **Advanced Hydrogel Technologies For Enhanced On-Tissue Protein Digestion and Improved Spatial Localization**

Although previous iterations of hydrogels have successfully performed spatially-directed proteomics analyses from tissue, improvements could still be made to all aspects of their use. The reduction of trypsin concentrations from 1  $\mu\text{g}/\mu\text{L}$  to 0.1  $\mu\text{g}/\mu\text{L}$  produced no statistical difference in the number of protein identifications. This can be beneficial to make the technology even more cost-effective, especially if many hydrogel experiments are being performed simultaneously. Further experiments revealed that increasing the percentage of polyacrylamide from 7.5% to 18% formed a more rigid polymer. The rigidity allowed for hydrogels to be fabricated from smaller diameter punch biopsies, reproducibly creating the first hydrogels of this type with diameters of 260  $\mu\text{m}$ . Alterations to the percentage of polyacrylamide showed no decrease in protein identifications, or in the molecular weight ranges of proteins identified. Reducing the diameter of the hydrogels did decrease the number of protein identifications, which is to be expected as less tissue is being sampled. However, even the smallest diameter hydrogels yielded ~670 confident identifications. Hydrogels performed as well as or better than LCM and tissue punches of the same area, which shows the power of performing digestions and extractions in one incubation step. When applied to the white matter and molecular layer within rat

cerebellum tissue sections, rich datasets were observed for each hydrogel. This again highlights the technology, providing around 1,000 protein identifications while maintaining their localization within the tissue.

### **Future Research Directions**

Detection of proteins from tissue with masses >17kDa using MALDI FTICR IMS represents a significant advancement in molecular imaging technologies; however, a vast number of endogenous proteins have even larger molecular weights. Diminished sensitivity for larger proteins is likely due to the difficulty in desorbing higher molecular weight analytes from tissue and limited ion transfer efficiencies of these analytes for many commercial source components (e.g., multipoles and ion funnels). This issue is not unique to MALDI FTICR IMS experiments, as the majority of proteins detected from tissue using MALDI-TOF platforms are typically <30kDa. Continuing to develop new methods for detecting and identifying proteins is critical to exposing the underlying biology that drives the images we collect. High mass accuracy and resolving power instrumentation enables such identifications to be made with high confidence.

Additionally, the detectable mass range can be extended by *in situ* tryptic digestion and imaging of tryptic peptides. Many hurdles still remain to be overcome, such as reduction and alkylation steps which are routinely used in in-solution digestion protocols. By breaking the cysteine bonds and allowing the protein to unfold, enzymes have better access to internal cleavage sites, improving overall sequence coverage. Heat-denaturing the tissue prior to digestion could provide a solution-free alternative, and has begun to be incorporated as an antigen retrieval step for FFPE IMS workflows. Additionally, more standard rehydration conditions would allow for better reproducibility from day to day and from person to person.

Modified trypsin able to withstand high temperatures would allow for more rapid digestion times, minimizing the chance of delocalization from the moisture in the incubation chamber.

Hydrogels have become highly useful tools for histology-driven analyses on a wide range of biological specimens, where specific anatomical features are targeted for direct profiling or identifications. However, as the targets of such analyses continue to become smaller and smaller, the hydrogel diameters will also need to decrease. Accurate placement of such hydrogels is important in experiments with very small spatial features. Manual manipulation is likely not feasible at these dimensions and the introduction of more precise equipment, such as micromanipulators, will improve this facet. Robotic manipulation would improve placement accuracy and precision, especially when used in conjunction with microscopy-directed targets. Alternatively, incorporating an array of hydrogels would allow for a multiplexed approach where hydrogels of interest within the array can be excised and subsequently analyzed. By incorporating the hydrogel technologies into proteomic workflows, robust and reproducible results can now be achieved at smaller dimensions, opening the door for targeting smaller anatomical features, such as specific substructures within tissues, or future clinical applications.

## **Conclusions**

In summary, high resolution MALDI IMS and spatially-directed proteomics experiments were used to improve protein identification confidence as well as provide alternatives to basic homogenization strategies. Methods have been developed to routinely image proteins on an FTICR, achieving  $m/z$  measurements of 17,000 and above. When comparing to top-down ETD fragmentation identifications, proteins were able to be matched to IMS ions with accuracies of less than 5 ppm. Peptide imaging was also improved, with similar sample preparation conditions

yielding robust peptide imaging datasets. Optimizing the incubation conditions resulted in better localization within the tissue section. Hydrogel technologies have also been advanced to target smaller biological regions, while still providing over 670 confident protein identifications. Hydrogels outperformed analogous LCM experiments and were comparable to traditional tissue homogenization approaches on the same amount of tissue.

These approaches can be incorporated into almost any protein-driven investigation to yield confident identifications with distinct imaging mass spectrometry patterns representative of the natural distributions within the tissue. High mass accuracy and resolution can be used to parse apart protein variations, such as isoforms, splice variants, or post-translationally modified forms. As hydrogel dimensions continue to decrease, smaller features within tissue can be targeted for unambiguous protein identifications. Scientific communities that study heterogeneous tissues, such as infectious disease and cancer research, would greatly benefit from these technological advancements to detect protein changes quickly, efficiently, and confidently. Understanding proteomic changes within complex systems is paramount to understanding biological processes like disease pathogenesis and progression.

APPENDIX A: Protein Identifications Unique to the "White Matter" Hydrogel (Cont'd)

272 Protein Identifications Unique to the "White Matter" Hydrogel									
<i>X! Tandem Rank</i>	<i>log(e)</i>	<i>log(l)</i>	<i>Accession</i>	<i>Description</i>	<i>Mr</i>	<i>Unique Peptides</i>	<i>Total Peptides</i>	<i>%(measured)</i>	<i>%(corrected)</i>
803	-16.2	4.58	HCN1_RAT	Potassium/sodium hyperpolarization-activated cyclic nucleotide-gated channel 1	102.4	3	3	4.6	9
807	-16	5	SEPT9_RAT	Septin-9	63.8	3	3	4.4	6
808	-15.9	4.64	GBRA6_RAT	Gamma-aminobutyric acid receptor subunit alpha-6	51.2	3	3	8.2	12
809	-15.9	5.28	RS26_RAT	40S ribosomal protein S26	12.9	3	3	20	36
814	-15.7	4.95	FIS1_RAT	Mitochondrial fission 1 protein	17	3	4	17	26
817	-15.6	5.05	RL23A_RAT	60S ribosomal protein L23a	17.7	3	4	17	37
818	-15.5	4.65	GCYB1_RAT	Guanylate cyclase soluble subunit beta-1	70.4	3	3	4.4	6
819	-15.5	4.6	MYPT1_RAT	Protein phosphatase 1 regulatory subunit 12A	115.2	3	5	3.6	6
821	-15.5	4.52	CPSM_RAT	Carbamoyl-phosphate synthase [ammonia], mitochondrial	164.5	3	3	3	5
823	-15.4	4.82	PDC6L_RAT	Programmed cell death 6-interacting protein	44	3	3	6.5	11
825	-15.3	4.84	BPNT1_RAT	3'(2'),5'-biphosphate nucleotidase 1	33.2	3	3	9.7	11
828	-15.1	4.62	DLC2A_RAT	Dynein light chain roadblock-type 1	10.9	2	2	12	13
831	-14.8	5	XKR4_RAT	XK-related protein 4	72.7	3	3	5.7	11
833	-14.7	5.04	PTBP2_RAT	Polypyrimidine tract-binding protein 2	57.5	3	3	5.8	11
834	-14.7	4.58	FAAA_RAT	Fumarylacetoacetase	45.9	2	2	6	9
837	-14.5	4.8	NMDZ1_RAT	Glutamate receptor ionotropic, NMDA 1	105.4	3	3	4.5	8
839	-14.4	5.06	NPM_RAT	Nucleophosmin	32.5	3	3	14	17
842	-14.3	4.53	CORO7_RAT	Coronin-7	48.9	2	3	5.6	8
844	-14.3	4.36	HBS1L_RAT	HBS1-like protein	74.7	3	3	7.7	10
845	-14.2	4.37	CLD11_RAT	Claudin-11	22	2	2	6.3	15
847	-14	4.58	CO1A2_RAT	Collagen alpha-2(I) chain	129.5	3	3	4.2	5
848	-14	4.82	CSPG2_RAT	Versican core protein	299.8	2	2	0.7	1
850	-13.8	4.57	IF5A1_RAT	Eukaryotic translation initiation factor 5A-1	16.7	2	2	22	27
851	-13.7	3.74	LAT2_RAT	Large neutral amino acids transporter small subunit 2	58.2	2	2	7.5	23
856	-13.3	4.35	TSC2_RAT	Tuberin	201.2	2	2	1.7	2
857	-13.2	4.39	PTBP1_RAT	Polypyrimidine tract-binding protein 1	59.3	2	3	6.7	11
858	-13.2	4.28	PHLPP_RAT	PH domain leucine-rich repeat protein phosphatase 1	183.2	2	2	1.2	2
859	-13.2	4.51	UCHL3_RAT	Ubiquitin carboxyl-terminal hydrolase isozyme L3	26.1	2	2	11	15
861	-13.1	4.39	NMT1_RAT	Glycylpeptide N-tetradecanoyltransferase 1	56.8	2	2	8.1	11
863	-13	4.27	CP2D1_RAT	Cytochrome P450 2D1	57.1	2	2	9.1	12
866	-12.8	4.73	SIRT2_RAT	NAD-dependent protein deacetylase sirtuin-2	39.5	2	2	5.1	6
870	-12.5	4.43	SQSTM1_RAT	Sequestosome-1	47.7	2	2	6.4	9
871	-12.5	4.25	CPNS1_RAT	Calpain small subunit 1	28.6	2	2	8.5	14
875	-12.2	4.99	DOCK9_RAT	Dedicator of cytokinesis protein 9	82.4	2	2	2.5	3
877	-12.1	4.61	S61A1_RAT	Protein transport protein Sec61 subunit alpha isoform 1	52.1	2	2	4.6	10
878	-12.1	4.23	ADCY2_RAT	Adenylyate cyclase type 2	123.2	2	2	2.1	4
879	-12.1	4.91	RL38_RAT	60S ribosomal protein L38	8.1	2	3	26	55
885	-12	4.36	PA1B3_RAT	Platelet-activating factor acetylhydrolase IB subunit gamma	25.8	2	2	12	14

APPENDIX A: Protein Identifications Unique to the "White Matter" Hydrogel (Cont'd)

272 Protein Identifications Unique to the "White Matter" Hydrogel									
<i>X! Tandem Rank</i>	<i>log(e)</i>	<i>log(l)</i>	<i>Accession</i>	<i>Description</i>	<i>Mr</i>	<i>Unique Peptides</i>	<i>Total Peptides</i>	<i>%(measured)</i>	<i>%(corrected)</i>
887	-12	4.7	ELOB_RAT	Transcription elongation factor B polypeptide 2	13.2	2	2	12	12
888	-12	4.45	CD81_RAT	CD81 antigen	25.9	2	3	8.1	23
890	-11.9	4.35	FBX6_RAT	F-box only protein 6	32.8	2	2	6.3	9
891	-11.9	4.38	CCD16_RAT	Zinc finger protein 830	41.6	2	2	5.9	8
892	-11.9	4.75	TCP4_RAT	Activated RNA polymerase II transcriptional coactivator p15	14.3	2	2	14	17
895	-11.8	4.34	A113_RAT	Alpha-1-inhibitor 3	163.7	2	2	1.8	3
898	-11.7	4.73	CPSF5_RAT	Cleavage and polyadenylation specificity factor subunit 5	26.2	2	2	11	16
901	-11.7	4.41	PGTB_RAT	Geranylgeranyl transferase type-2 subunit beta	36.8	2	2	13	27
902	-11.6	4.77	RL17_RAT	60S ribosomal protein L17	21.3	2	2	12	20
904	-11.5	3.94	ATF2_RAT	Cyclic AMP-dependent transcription factor ATF-2	52.3	2	2	10	22
905	-11.5	4.67	TBAP_RAT	Protein Dr1	19.4	2	2	11	18
908	-11.4	4.4	AMPD3_RAT	AMP deaminase 3	88.4	2	2	2.6	4
911	-11.3	4.29	NOP5_RAT	Nucleolar protein 58	60	2	2	5.2	8
912	-11.3	4.5	RL15_RAT	60S ribosomal protein L15	24	2	2	10	15
913	-11.3	4.42	NDE1_RAT	Nuclear distribution protein nudE homolog 1	38.5	2	2	6.4	8
917	-11.2	4.61	LMAN1_RAT	Protein ERGIC-53	57.9	2	2	4.1	7
918	-11.1	4.55	SVIP_RAT	Small VCP/p97-interacting protein	8.2	2	2	29	42
922	-11.1	4.59	SCN2B_RAT	Sodium channel subunit beta-2	24.1	2	3	11	21
923	-11.1	4.21	GCP60_RAT	Golgi resident protein GCP60	60.3	2	2	4.6	7
924	-11	4.59	NUDC2_RAT	NudC domain-containing protein 2	17.7	2	2	17	22
925	-11	4.37	UBE4A_RAT	Ubiquitin conjugation factor E4 A	122.3	2	3	2.4	4
927	-10.9	4.79	RS4X_RAT	40S ribosomal protein S4, X isoform	29.4	2	3	8	11
928	-10.9	4.65	RL9_RAT	60S ribosomal protein L9	21.9	2	2	14	26
929	-10.9	4.79	RBM4B_RAT	RNA-binding protein 4B	40	2	2	4.8	7
930	-10.8	4.28	TOP2A_RAT	DNA topoisomerase 2-alpha	173.1	2	2	1.9	3
931	-10.8	4.23	UBQL1_RAT	Ubiquilin-1	62	2	2	4.3	10
932	-10.8	4.18	CLIC4_RAT	Chloride intracellular channel protein 4	28.5	2	2	16	20
933	-10.8	4.41	PSB3_RAT	Proteasome subunit beta type-3	22.9	2	2	14	23
935	-10.8	4.73	UB2D4_RAT	Ubiquitin-conjugating enzyme E2 D2B	16.6	2	2	17	57
937	-10.7	4.96	CYTB_RAT	Cystatin-B	11.2	2	3	31	40
939	-10.7	4.76	FHL1_RAT	Four and a half LIM domains protein 1	31.9	2	2	6.4	9
941	-10.7	5.03	BAF_RAT	Barrier-to-autointegration factor	10	2	3	42	52
942	-10.7	4.48	SH3K1_RAT	SH3 domain-containing kinase-binding protein 1	78	2	2	3.8	5
943	-10.7	4.65	TCTP_RAT	Translationally-controlled tumor protein	19.4	2	2	5.2	9
944	-10.7	4.09	ABCA2_RAT	ATP-binding cassette sub-family A member 2	270.8	2	2	1.7	3
945	-10.7	3.91	GMPRI1_RAT	GMP reductase 1	37.5	2	2	8.1	11
946	-10.6	4.15	CDK9_RAT	Cyclin-dependent kinase 9	42.7	2	2	6.2	8
947	-10.6	4.46	HSPB1_RAT	Heat shock protein beta-1	22.9	2	2	11	16

APPENDIX A: Protein Identifications Unique to the "White Matter" Hydrogel (Cont'd)

272 Protein Identifications Unique to the "White Matter" Hydrogel									
<i>X! Tandem Rank</i>	<i>log(e)</i>	<i>log(l)</i>	<i>Accession</i>	<i>Description</i>	<i>Mr</i>	<i>Unique Peptides</i>	<i>Total Peptides</i>	<i>% (measured)</i>	<i>% (corrected)</i>
951	-10.5	4.68	CYH1_RAT	Cytohesin-1	46.2	2	2	8	11
953	-10.4	4.55	D2HDH_RAT	D-2-hydroxyglutarate dehydrogenase, mitochondrial	58.8	2	2	5	8
956	-10.3	4.44	RS27_RAT	40S ribosomal protein S27	9.3	2	2	27	33
957	-10.3	4.47	B2MG_RAT	Beta-2-microglobulin	13.7	2	2	17	25

## ***Permanent Address***

320 Old Hickory Blvd

Unit 1808

Nashville, TN 37221

## ***University Address***

Mass Spectrometry Research Center

Vanderbilt University

PMB 407916

Nashville, TN 37240-7916

## **Education**

- 2010-Present** Vanderbilt University, Nashville, TN  
Doctor of Philosophy in Chemistry; Anticipated Graduation: April 2016  
Graduate Research Advisor: Dr. Richard M. Caprioli  
Graduate Thesis: *High Mass Accuracy Coupled to Spatially Directed Proteomics for Improved Protein Identifications in Imaging Mass Spectrometry Experiments*  
GPA: 3.69
- 2005-2009** Georgia Institute of Technology, Atlanta, GA  
Bachelor of Science in Chemistry (Research Option) with Honors  
Certificate in Social/Personality Psychology  
Undergraduate Research Advisor: Dr. Facundo M. Fernández  
Undergraduate Thesis: *Amino Acid Profiling by Reactive Desorption Electrospray Ionization Tandem Mass Spectrometry (DESI-MS/MS)*  
GPA: 3.23

## **Laboratory Experience**

- 2010-Present** **Graduate Research Assistant** (Vanderbilt University Department of Chemistry)
- Developed sample preparation and instrumentation methods to perform robust protein IMS on a 15T MALDI FTICR
  - Optimized on-tissue digestion methods and incubation procedures to ensure sufficient enzymatic digestion as evaluated by MALDI IMS
  - Performed localized microextracts for LC-MS/MS protein and peptide identifications to correlate to ions observed in MALDI FTICR IMS experiments

## David G. Rizzo

- Thoroughly investigated functional properties of trypsin-filled polyacrylamide hydrogels to improve reproducibility and reduce the diameter for spatially-targeted proteomics experiments
  - Evaluated trypsin concentration, polyacrylamide percentages, and hydrogel diameter based on the number of protein identifications
  - Applied optimized hydrogel technology to rat cerebellum substructures to differentially identify proteins based on hydrogel placement

**2008-2009 Undergraduate Researcher** (Georgia Institute of Technology Department of Chemistry)

- Developed MS methods for the detection of amino acids by reactive DESI-MS/MS
- Assessed binding efficiencies of reactive DESI additives, such as crown ethers and  $\beta$ -cyclodextrin

### Presentations (Presenting Author Underlined)

- 12) High Mass Accuracy Coupled to Spatially-Directed Proteomics for Improved Protein Identifications in Imaging Mass Spectrometry Experiments (Poster) - David G. Rizzo, Jeffrey M. Spraggins, Jessica L. Moore, Kristie L. Rose, Richard M. Caprioli  
*The NATO Science for Peace and Security Program - Advanced Study Institute* (Calabria, Italy, 2016)
- 11) Developing and Assessing Polyacrylamide Hydrogel Technologies for Improved Protein Extraction from Targeted Regions of Biological Tissues (Poster) - David G. Rizzo, Jessica L. Moore, Boone M. Prentice, Jeremy L. Norris, Richard M. Caprioli  
*63rd ASMS Conference on Mass Spectrometry & Allied Topics* (St. Louis, MO, 2015)
- 10) Spatial Extraction and Enrichment of Phosphopeptides from Tissues Using Hydrogels Containing Metal Ion-Functionalized Nanopolymers (Poster) – M. Lisa Manier, Jamie L. Wenke, David G. Rizzo, Jeremy L. Norris, Kevin L. Schey, Richard M. Caprioli  
*63rd ASMS Conference on Mass Spectrometry & Allied Topics* (St. Louis, MO, 2015)
- 9) Top-Down and Bottom-Up Analyses of Proteins on the *Same Tissue Section* Using High Mass Resolution Imaging Mass Spectrometry (Poster) - David G. Rizzo, Jeffrey M. Spraggins, Kristie L. Rose, Richard M. Caprioli  
*62nd ASMS Conference on Mass Spectrometry & Allied Topics* (Baltimore, MD, 2014)
- 8) Imaging and Accurate Mass Identifications of Intact Proteins above 10kDa Using Multiply Charged Ions and High Resolution MS (Poster) – David G. Rizzo, Jeffrey M. Spraggins, Kristie L. Rose, Richard M. Caprioli  
*61st ASMS Conference on Mass Spectrometry & Allied Topics* (Minneapolis, MN, 2013)
- 7) Visualizing Biomolecular Modifications in Tissue: Integrating Mass Difference ( $\Delta$ - $m/z$ ) Scanning Algorithms and MALDI FT-ICR Imaging Mass Spectrometry (Oral) - Jeffrey M. Spraggins; Raf Van de Plas; Kerri J. Grove; David G. Rizzo; Richard M. Caprioli  
*61st ASMS Conference on Mass Spectrometry & Allied Topics* (Minneapolis, MN, 2013)
- 6) Integrating the Spatial Domain and Top-Down Proteomics using Mass Accuracy: Enhancing Protein Mapping for Biological Applications (Oral) – Jeffrey M. Spraggins, David G. Rizzo, Jessica L. Moore, Eric P. Skaar, Richard M. Caprioli  
*ASMS Annual Sanibel Conference: Top Down Proteomics* (St. Pete Beach, FL, 2013)
- 5) Imaging of Proteins Up to 80kDa in Biological Tissues by MALDI MS (Poster) – David

## David G. Rizzo

- G. Rizzo**, Erin H. Seeley, Junhai Yang, Richard M. Caprioli  
*60th ASMS Conference on Mass Spectrometry & Allied Topics* (Vancouver, BC, Canada, 2012)
- 4) Amino Acid Profiling in Biological Mixtures by Reactive Desorption Electrospray Ionization Tandem Mass Spectrometry (DESI MS/MS) (Poster) - **David G. Rizzo**, Leonard Nyadong, Facundo M. Fernández  
*42nd Annual Southeast Regional ACS Undergraduate Research Conference* (Kennesaw State University, Kennesaw, GA, 2010)
  - 3) Amino Acid Profiling in Serum by On-plate Solid Phase Extraction and Multicapillary Desorption Electrospray Ionization Mass Spectrometry (DESI MS) (Poster) – **David G. Rizzo**, Leonard Nyadong, Facundo M. Fernández  
*Undergraduate Research Opportunities Program (UROP) Spring Symposium* (Georgia Institute of Technology, Atlanta, GA, 2009)
  - 2) Amino Acid Profiling in Biological Mixtures by Reactive Desorption Electrospray Ionization Tandem Mass Spectrometry (DESI MS/MS) (Poster) - **David G. Rizzo**, Leonard Nyadong, Facundo M. Fernández  
*Georgia Institute of Technology Chemistry REU Summer Program Symposium - Aquatic Chemical Ecology* (Georgia Institute of Technology, Atlanta, GA, 2009)
  - 1) Amino Acid Profiling in Biological Mixtures by Reactive Desorption Electrospray Ionization Tandem Mass Spectrometry (DESI MS/MS) (Poster) - **David G. Rizzo**, Leonard Nyadong, Asiri S. Galhena, Facundo M. Fernández  
*Herty Medalist Undergraduate Research Symposium* (Morehouse College, Atlanta, GA, 2009)

### Publications

- 2015** Jeffrey M. Spraggins, **David G. Rizzo**, Jessica L. Moore, Kristie L. Rose, Neal D. Hammer, Eric P. Skaar, and Richard M. Caprioli, *Journal of the American Society for Mass Spectrometry*, **2015**, 26 (6), 974-85. “MALDI FTICR IMS of Intact Proteins: Using Mass Accuracy to Link Protein Images with Proteomics Data”
- 2016** Jeffrey M. Spraggins, **David G. Rizzo**, Jessica L. Moore, Michael J. Noto, Eric P. Skaar, and Richard M. Caprioli, *Proteomics*, **2016**, “Next-generation Technologies for Spatial Proteomics: Integrating Ultra-high Speed MALDI-TOF and High Mass Resolution MALDI FTICR Imaging Mass Spectrometry for Protein Analysis”
- In Draft* **David G. Rizzo**, Boone M. Prentice, Jessica L. Moore, Jeremy L. Norris, Richard M. Caprioli. “Advanced Hydrogel Technologies for Enhanced On-Tissue Protein Digestion and Improved Spatial Localization”

### Teaching Experience

- 2015** Vanderbilt Internal Fundamental Mass Spectrometry Lecture Series Lecturer
- “Fundamentals of Ion Mobility”
- 2015** Vanderbilt Aspirnaut™ HS Summer Internship Program Research Mentor
- 2013-2015** Advanced Imaging Mass Spectrometry (AIMS) Laboratory Course – Workshop Leader
- “Instrumentation: Ion Mobility” 2013-2015

## David G. Rizzo

- “Matrix Application: Robotic Spraying” 2013-2015
  - “Sample Preparation: Washing and Staining” 2013
- 2010-2011** Vanderbilt University Chemistry Department Teaching Assistant
- Chem 295: Advanced Integrated Laboratory (Senior Capstone Lab) – Spring 2011
  - Chem 104A: General Chemistry Lab – Fall 2010

### Awards

- 2015-2016** Aegis Sciences Fellowship in Chemistry at Vanderbilt University
- 2009** Herty Medalist Undergraduate Research Symposium Award
- 2009** Georgia Institute of Technology Chemistry REU Summer Program  
Aquatic Chemical Ecology
- Fall 2008- Spring 2009;  
Fall 2005-Spring 2007** Georgia Institute of Technology Dean’s List

### Leadership Experience/Activities

- 2012-2013** Vanderbilt University Chemistry Department Warren Lecture Search Committee
- 2012-2013** Vanderbilt University Chemistry Graduate Student Association
- Founding member and analytical chemistry representative
  - Liaison to the department of chemistry faculty and administration
- 2011-Present** American Society for Mass Spectrometry Member
- 2009-2011** American Chemical Society Member
- 2008-2009** Connect with Tech Host
- Hosted high school students interested in coming to Georgia Tech, showcasing campus, classes, and student life
  - Student life Q&A panelist for potential students and parents
- 2006-2009** Georgia Tech Interfraternity Council (*Homecoming Events Committee, Fall 2006; Greek Week Events Committee, Spring 2007; Homecoming Events Committee Chair, Fall 2007; Greek Neighborhood Association Chair, Fall 2008-Spring 2009; Earth Day Planning Committee, Spring 2009*)
- 2006-2009** Phi Sigma Pi National Honor Fraternity – Epsilon Theta Chapter (*Charter Member, Fall 2006; Initiate Education Officer, Spring 2007-Spring 2008*)
- 2005-2009** Sigma Nu Fraternity – Gamma Alpha Chapter (*Campus Involvement Chair, 2006; Kitchen Administrator, Fall 2006-Fall 2007; Honor Council: Member, Spring 2006-Fall 2009; Chair, Fall 2007-Fall 2008; Lieutenant Commander/Vice President, Fall 2007-Fall 2008; Housing Manager, Fall 2008-Fall 2009*)

## David G. Rizzo

### Instrumentation, Skills, and Software

- Tissue Sectioning and Handling
  - Thermo HM325 Microm Microtome
  - Leica CM 3050S, Leica CM 1900, and Thermo NX70 Cryotomes
  - Leica CM 3600 XP Cryomicrotome
  - Zeiss PALM MicroBeam Laser Capture Microdissection (LCM)
  - FFPE tissue deparaffination and antigen retrieval
  - Tissue washing
  - Histological staining
- MALDI Matrix Application Systems
  - HTX TM-Sprayer robotic sprayer
  - Labcyte Portrait 630 acoustic spotter
  - Home-built sublimation apparatus
  - Thin layer chromatography (TLC) hand sprayer apparatus
- MALDI TOF and TOF/TOF MS
  - Bruker autoflex, ultrafleXtreme, rapifleX MALDI Tissue typer
- MALDI FTICR MS
  - Bruker Solarix 9.4T & 15T
- Quadrupole-ion mobility-oTOF MS
  - Waters Synapt G2 and G2-Si
- HPLC
  - Waters nanoAcquity
  - Waters 2690 HPLC
- Bruker flexControl, flexAnalysis/dataAnalysis, flexImaging, ClinProTools
- Waters MassLynx, Driftscope, HDImaging
- Thermo Xcalibur
- mMass Open Source Mass Spectrometry Tool
- Scaffold Proteomics Viewer Software
- Vulcan Analytical Protalyzer Proteomics Software
- OriginLab Data Analysis and Graphing Software
- ChemDraw
- Microsoft Office
